Topic: 20015 Message: 20030

Thanks to all who responded to my post and for your advice.

Plan B is to use three ten foot masts from Radio Shack http://bit.ly/r8C0MM

Again, I plan to guy it at thirty feet and fifteen feet.

The antenna I plan to use is a 100 watt LnR Precision EF-40/20.

Thanks again,
Tom WX1YZ

hi Bill,

I built a Moxon with # 12 THHN solid wire,
it worked so well that I built a second one
using 3/8" aluminum tubing T6061 with a pvc frame.

http://www.kg4jjh.com/pdf/6m%20Moxon.pdf

The above is nice plans but you can build it
the way you like, just use the same dimensions.

Topic: 20012 Message: 20039

That is correct or it is the standard roll of 16,14 or 12 ga wire on a roll at Home Depot, Lowe’s or your local hardware store that you run in conduit or make a antenna with. If you want to remove the insulation buy the solid it is easier to work with when removing insulation. If you have a 2x4 laying around I can tell you how to make a neat wire stripper. I strip RG-11 CATV feed for the center copperweld with mine.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-05 00:10:25 UTC
From: kd8dvy@ymail.com
Topic: 19957 Message: 20041

When I work NVIS I can get about 350 miles or so and that is on 40/80 meter and my antenna center is 12-15' and the ends are about 2-4' off the ground.

This is where things get really interesting. I am a purely QRP SSB operator and it still works. There is a group called LXpedition that is only local to ATLANTA, GA and that is all we do. You may want to contact the Moderator and ask him how you can do something local to your area.

This is one of my portable set-ups.

20045. Re: [ham-antennas] Re: Portable / Mobile NVIS Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-05 00:57:08 UTC
From: dean
Topic: 19957 Message: 20045

As soon as I get the stud for my 3/8 x 24 mount I'll be doing a 40 / 75 meter NVIS but up at 12 to 15' off the ground. My vehicle will be the ground part of the antenna so should be interesting on how long the wire will be. I've been trying to convince our local SAR (Search and Rescue) group to go NVIS on 40 meters, but of course that would mean more generals and higher licenses. We generally don't do search's after dark. We are always in nasty terrain.

I've never tried QRP at all. I'm mostly 100 W's of power mobile and portable and 500 W's in the shack.

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Re: Portable / Mobile NVIS Antennas

When I work NVIS I can get about 350 miles or so and that is on 40/80 meter and my antenna center is 12-15' and the ends are about 2-4' off the ground.

This is where things get really interesting. I am a purely QRP SSB operator and it still works. There is a group called LXpedition that is only local to ATLANTA, GA and that is all we do. You may want to contact the Moderator and ask him how you can do something local to your area.

This is one of my portable set-ups.

The Isopole is two conical ground sections and a quarter wave radiator.
The mast part used to be not included. I have had a couple of these and
they worked just fine. We even used one for a repeater antenna back east.

Nope,

I had several.

The cones equal to the ground plane, but the lower cone and the
radiating element top are 5/8 wave long. so it is an extended double
zepp dipole vertically polarized. With another cone to help cut off more
currents from going down the mast.

OK , I don't have a picture of it but I could take one if needed. Everything I do is by a basic guide line of **SWAG. First step it to take a section of scrap 2x4 wood, drill a hole into the 1.5 side, thru the 3.5 dimension, about 1.5 to 2" from the end. The diameter of the hole is a slip fit for the cable/wire you are going to use. For the RG-11 I use a 7/16 hole (.437) for the 405 dia cable. Next step is the take a hacksaw or any thin bladed saw and cut a slot down to the hole, off center the amount of the insulation would be great but not 100% a necessity. Place a utility knife blade in the slot far enough to cut the insulation but not nick the wire. Apply a "C" clamp to the top of the 2x4 to hold the blade in place, or you could get fancy and put a bolt thru the 2x4 to secure the blade. Now place the 2x4 in a vice, place your roll of coax on a broom handle supported by two jack stands and you can run off enough for a 80M dipole in no time flat. With the insulation cut be it RG-11 or 12ga you can strip the weakened insulation off the wire. This works great will all but solid dielectric coax. With THHN once the insulation is highly damaged by the blade on one side it is easy to pull off, unless you are making a 160 EZD.

Rich , Kd0zz

From: Richard Schmuke
Topic: 20012 Message: 20052

OK, here is a picture of a piece of hard wood set up for stripping some RG-6. It has smaller copperweld in it. The blade is set deeper into the wood in real use. I have it closer to the edge for show and tell. I told you I do things different each time. Picture is #42 in the Kd0zz album. I used bigger wood for the RG-11 CATV because of the tougher shield.

Ever heard of a "jokari" knife??
It is a wire stripper that all electricians here in dl use for stripping insulation off ...
It is a grip with a very small knife in it
the small bade can turn around in the grip
and so you can cut around the insulation ... and parallel to it (longitudinal)
deepness can be controlled with a small screw at the lower end of the grip
http://www.jokari.de/fileadmin/product_db/anleitungen/B10160.pdf

jokari makes many different wire strippers (and the best on the market *g*)

There is also a cable stripper that consists of a folded piece of steel with a small tab on it and you just hold it down and pull and it cuts the cable lengthwise.

I don't have one so no picture.

Subject: AW: [ham-antennas] Re: 6 METER ANTENNAS (wire stripper)

Ever heard of a "jokari" knife??
It is a wire stripper that all electricians here in dl use for stripping insulation off ...
It is a grip with a very small knife in it
the small bade can turn around in the grip
and so you can cut around the insulation ... and parallel to it (longitudinal)
deepness can be controlled with a small screw at the lower end of the grip
http://www.jokari.de/fileadmin/product_db/anleitungen/B10160.pdf

jokari makes many different wire strippers (and the best on the market *g*)

From: Joe
Topic: 20056 Message: 20056

OK now ignore HOA's and covenants, and all that. I'm thinking like county level ordinances here.

Now do any of these laws that talk about towers and restrictions placed on them by a county zoning commission. Do they only apply to permanent towers?

What about a tower you can claim as being temporary?

IE: no concrete?

Guy anchors are screw in anchors.

Tower base is a pad only that can be removed easily. Nothing is "Set in concrete" pun intended. do the laws still apply then?

If it's on wheels it's not a a structure, otherwise almost all local
zoning regulations vary, in my county a structure used solely for HAM radio
is exempt from all regulations. In the three cities in this county severe
limitations apply.

OK, here is a picture of a piece of hard wood set up for stripping some RG-6. It has smaller copperweld in it. The blade is set deeper into the wood in real use. I have it closer to the edge for show and tell. I told you I do things different each time. Picture is #42 in the Kd0zz album. I used bigger wood for the RG-11 CATV because of the tougher shield.

Rich , Kd0zz

Subject: RE: [ham-antennas] Re: 6 METER ANTENNAS (wire stripper)

Pictures please!!

On Wed Oct 5th, 2011 11:59 AM CDT Richard Schmuke wrote:

>OK , I don't have a picture of it but I could take one if needed. Everything I do is by a basic guide line of **SWAG. First step it to take a section of scrap 2x4 wood, drill a hole into the 1.5 side, thru the 3.5 dimension, about 1.5 to 2" from the end. The diameter of the hole is a slip fit for the cable/wire you are going to use. For the RG-11 I use a 7/16 hole (.437) for the 405 dia cable. Next step is the take a hacksaw or any thin bladed saw and cut a slot down to the hole, off center the amount of the insulation would be great but not 100% a necessity. Place a utility knife blade in the slot far enough to cut the insulation but not nick the wire. Apply a "C" clamp to the top of the 2x4 to hold the blade in place, or you could get fancy and put a bolt thru the 2x4 to secure the blade. Now place the 2x4 in a vice, place your roll of coax on a broom handle supported by two jack stands and you can run off enough for a 80M dipole in no time
flat. With the insulation cut be it RG-11 or 12ga you can strip the weakened insulation off the wire. This works great will all but solid dielectric coax. With THHN once the insulation is highly damaged by the blade on one side it is easy to pull off, unless you are making a 160 EZD.

Hi rich
Yepp ... it IS a great tool ...
They make different strippers for different work
But most of the "jokari" knifes can be used to make that longitudinal cut
Maybe others find it useful too

Ron is right: the only thing that is constant is change.

Requirements vary radically from one locality to another. Some include any structure, whether temporary or permanent, others don't.

The best bet is to call your local (county or city) zoning board and the corresponding permit office. The zoning board will tell you the rules, and the permit office will tell you what rules are enforced, and in what way.

Good luck.

We are much better off in Canada with respect to amateur communication towers. It is a Federal jurisdiction and local municipalities cannot pass enforceable by-laws to prevent the putting up of towers by radio amateurs. If one signs an agreement with a particular development that prohibits such towers then the right is probably waived. Otherwise the airwaves are a federal jurisdiction and as long as one meets the federal requirements there is not much local municipalities can do to prevent the erection of a tower. There are height restrictions that require special permission but for most smaller towers are allowed. That is not to say that one will not get into issues with neighbors who object to the tower, but in the end radio amateurs win out. Many municipalities have tried to prevent amateurs from erecting towers, but in the end they find out that they do not have jurisdiction over them.

Joe,

Your question is best answered by your county building and zoning department. They are the ones who can definitively answer questions that apply to /your/ situation. Everything else is just speculation. Sometimes the info and forms are online.

That said, if you intend to install a tower, there is LOTS more to consider than permitting. I highly recommend 'Up The Tower' by Steve Morris K7LXC (www.championradio.com). Steve's book pointed me in the right direction for answers to questions I had. It also informed me where to find answers to questions I didn't know I had. Steve also moderates and posts to the Tower Talk email reflector (http://lists.contesting.com/mailman/listinfo/towertalk).

As of about a week ago, my tower permit process is started. The permit and its associated costs (PE paperwork) is not insignificant but, I'm covered in the event of trouble. This includes loss/liability, and troublemaker neighbors. This was all covered in K7LXC's book - the best $35 you can invest toward your tower.

20065. Re: Portable / Mobile NVIS Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-06 22:38:02 UTC
From: Tom
Topic: 19957 Message: 20065

After a week of experimenting.
Testing is with myself and another station 40 miles away, but over a mountain. We know no ground wave is working. Our end goal is to have reliable, portable low power NVIS comms less than 200 miles.

First we both tried a Hamstick "T" dipole arrangement mounted on a tripod 8 feet high on 40M with no success. No QSO even at 100 watts.

Then we tried 64 ft wire dipoles for 40 meters. At first we had the dipoles at 8 feet high, and heard very faint copy at 100W, and none at 50W. At the same time I was having great qso with people 400 to 1000 miles away, so that told me my radiating lobes were still too shallow.

Then we kept lowering the dipoles until we found a sweet spot for 40 Meters. Look like 3 feet high at the center and 2 feet high at the ends, just supported with wood stakes. Now we have good copy QSO at 5 WATTS SSB! So now we have 40 and 60 meters licked. 80 meters showed no signal- I'm thinking the dipole needs to be 2X higher for 80M.

Now that we have a handle on antenna height, one of us will go back to the Hamstick arrangement, only lower, and try again.

The next step will be trying PSK at less than 5 watts.

I'm looking into other portable NVIS antennas, some are dual autotune screwdrivers, some are just mil-spec loaded coils.

To be continued.

Subject: [ham-antennas] Re: Portable / Mobile NVIS Antennas

After a week of experimenting.
Testing is with myself and another station 40 miles away, but over a mountain. We know no ground wave is working. Our end goal is to have reliable, portable low power NVIS comms less than 200 miles.

First we both tried a Hamstick "T" dipole arrangement mounted on a tripod 8 feet high on 40M with no success. No QSO even at 100 watts.

Then we tried 64 ft wire dipoles for 40 meters. At first we had the dipoles at 8 feet high, and heard very faint copy at 100W, and none at 50W. At the same time I was having great qso with people 400 to 1000 miles away, so that told me my radiating lobes were still too shallow.

Then we kept lowering the dipoles until we found a sweet spot for 40 Meters. Look like 3 feet high at the center and 2 feet high at the ends, just supported with wood stakes. Now we have good copy QSO at 5 WATTS SSB! So now we have 40 and 60 meters licked. 80 meters showed no signal- I'm thinking the dipole needs to be 2X higher for 80M.

Now that we have a handle on antenna height, one of us will go back to the Hamstick arrangement, only lower, and try again.

The next step will be trying PSK at less than 5 watts.

I'm looking into other portable NVIS antennas, some are dual autotune screwdrivers, some are just mil-spec loaded coils.

To be continued.

governmental restrictions are much easier to deal with the FCC has
exercised its power to partially preempt state and local laws regulating
tower and antenna restrictions to provide that those governmental entities
must provide such reasonable accommodations as re necessary to allow Hams
effective use of their spectrum

Yeah I know all about it.

Thing is in this county gravity must behave in weird ways. Most of
their ordnance is OK. I can go even as high as 75 feet without having
to get special permission. BUT

They have one part of the ordnance that makes absolutely no sense at
all. and it is extremely obvious that whoever wrote it has never ever
seen a tower fall down.

The tower must be located no closer to anty property bopundary by at
least 1.5 times the height of the tower.

so a 50 foot tower needs to be 75 feet away from the property line.

I guess when it falls down it gets extra energy and can jump the extra
25 aso it can reach the property line.

Here in dl the tower has to be half its height from the property line
Maybe here in dl all towers break in the center before falling down ...
Then the lower half falls to the property line and the upper half folds back
on the lower half :-)

That actyually makes much more sence, go on you tube and do tower collapse,
http://www.youtube.com/watch?v=tww3jF2NcdE
They rarely fall 1/2 their height. and never ever more than their height.

20074. Re: [ham-antennas] Questions about using schedule 40 black iron pipe for antenna mast

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-08 00:40:58 UTC
From: From the desk of Allan Bell
Topic: 20015 Message: 20074

Ace Hardware offers Channel Master telescopic masts or you can order directly from the Channel Master website, channelmasterstore.com

Channel Master Product Numbers are as follows:
20 FT - CM 1820
30 FT - CM 1830
40 FT - CM 1840
50 FT - CM 1850

Allan

20075. TLW Program

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-08 00:40:34 UTC
From: W3GQ
Topic: 20075 Message: 20075

Does anyone know if the TLW program (supplied with the ARRL Antenna Book, 19th edition and later) is available anywhere other than by purchasing the handbook?

Thanks,

Paul, W3GQ

20076. FW: [ham-antennas] Questions about using schedule 40 black iron pipe for antenna mast

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-08 00:56:42 UTC
From: KA9EGW
Topic: 20076 Message: 20076

I don't see it on www.acehardware.com, which leads me to believe it may be a one-off, or a new-old-stock discontinued part. I just happened to notice it there in the rack next to the electrical conduit. It's a small, likely franchise, Ace, not a big chain box company-owned, I don't think.

However, google shopping found it at, among other places, Ace Superstore:

http://www.google.com/products/catalog?q=telescoping+antenna+mast&rls=com.microsoft:en-us&oe=UTF-8&startIndex=&startPage=1&um=1&ie=UTF-8&tbm=shop&cid=12082319903449134319&sa=X&ei=QIWPTuSmH-e0sQKkjImlAQ&ved=0CHEQ8wIwAA#

or one can order it direct from channelmaster:

http://www.channelmasterstore.com/TV_Antenna_Mast_p/cm-1830.htm

Schedule 40 black iron pipe is not an amateur standard for mast building.
it is extremly heavy and your gas pipe fitter would use this for natural gas or propane service after your gas meter
.
it would be heavier than most light duty towers and may cause issues with mast support and rotor support plate in the tower top section depending on your tower used except heavy duty telcom communications towers.

You dont want to go there unless you have a big bank roll can afford a crane etc for constuction

I can second that- I had a 100 foot tower that I put up by myself, using a jin pole. it had a 3 element tribander with a 11 element 2 meter beam above it. when your working on a tower you have about half of the lifting power you do working on the ground and your feet are 12-18 inch apart depending on the size tower. if your going to all of the trouble take your time,spend a little extra money and do it right.

I found this page, http://fermi.la.asu.edu/w9cf/tran/index.html
hopefully it'll work. I put "Transmission Line for Windows" in Google and I got a whole slew of hits.

Another one that pretty much looks like the program.
http://www.antennex.com/shack/Dec04/tlnw.htm

I just did the looking and maybe you can take it a bit further. I imagine all programs found on the ARRL CD can be found elsewhere. Hopefully this was somewhat helpful.

One of the more common programs is TLD (Transmission Line Details) by AC6LA. You can obtain a copy at no cost by visiting Dan's web site (http://www.qsl.net/ac6la/).

It depends:
How high? Length of tube?
What diameter of pvc tube used
Several tubes telescopic to get higher?
Guyed?

Why such a major price differance if they are the same product?
channel master web page $129.99
<http://www.channelmasterstore.com/TV_Antenna_Mast_p/cm-1830.htm>

google product search $73
<http://www.google.com/products/catalog?q=telescoping+antenna+mast&rls=com.microsoft:en-us&oe=UTF-8&startIndex=&startPage=1&um=1&ie=UTF-8&tbm=shop&cid=12082319903449134319&sa=X&ei=QIWPTuSmH-e0sQKkjImlAQ&ved=0CHEQ8wIwAA#>
I think I would be VERY leary of product quality!

Just my $0.02 worth (You get what you pay for) or is it a "China" tinfoil mast?

look around for people changing to cable or satelite service and get the old TV antennas . if they are in a deep fringe area the antennas are fairly large .

Topic: 20090 Message: 20094

I do the same thing. Collect any aluminum antennas I can, with an eye on making them into ham band antennas.
bear in mind, TV antennas are good for parts, but often not as durable as commercial and ham antennas. Plus are not cut for any of the ham bands.
an antenna cut for the old TV channel 2 would need elements made longer for 6 meters, and the UHF sections are usually too short for 70 centimeters.
some might work on 2 meters, but still might need work.
as for durability, I lost 1/2 an element on the TV antenna I have up. The plastic broke on one side. I did find the element and put it aside.
I have a couple of former 11 meter antennas, one I plan to either fix for 10 meters, or convert to 6 meters. the other is an odd antenna, horizontal elements, shaped in a "U" shape, made for use on a van roof. Claimed to be vertically polarized, though I don't see how. It could convert to 10, or even 6.
I considered making it into a square (like a squalo) for an omni 6 meter. It used a trombone capacitive coupled match, and a fast check with my analyzer shows it to be resonant on 11. making a mount for a squalo will be my challenge, and getting it resonant on 6. the trombone I can modify, having used teh same kind for 2 meters, and having a commercial antenna for 70 Cm that uses a similar type.
really old single band yagis made for TV can be converetd. One for channle 6 could be cut down for 2 meters, one for 2 enlarged for 6, and a channel 13 cut down for 1 1/4 meters (222-225 Mhz).
CB verticals can often be modified for 10, or 12 meters, some even for 20 or 17 meters. also, keep an eye out for working TV antenna rotors.
I used one with a large 10 meter beam years ago, and more recently, for a 4 element 6 meter beam, with a 2 meter beam mounted above it.
I also hope to get my hands on a tower from a TV antenna system, but not holding my breath.
oh yes, some people have been misled to think that their older TV antenna will not work with the new digital TV. LOL....

Be careful when comparing prices, sometimes the low one doesn't include tax and shipping. If both are base prices then the higher seller is making more profit, maybe.

It used to be that old CB directional were mounted all over the place, but I have been looking lately with little luck. Many have gone the way of the scrap yards, and so few fool with the CB equipment anymore. I have my eye on an 11 meter omnidirectional that can be adjusted easy enough for 10. Can always use it to monitor with. I should have a new to me rig by next week, a Yaesu 301D with speaker, power supply, and the antenna tuner. Did some horse trading and spent a little money to get it, I hope it works as well as it looks. I guess I will luck up one day and find a nice old beam and clean it up and use it for more constructive purposes. The antenna rotors I had really forgotten about, but that is a good idea.

It used to be that old CB directional were mounted all over the place, but I have been looking lately with little luck. Many have gone the way of the scrap yards, and so few fool with the CB equipment anymore. I have my eye on an 11 meter omnidirectional that can be adjusted easy enough for 10. Can always use it to monitor with. I should have a new to me rig by next week, a Yaesu 301D with speaker, power supply, and the antenna tuner. Did some horse trading and spent a little money to get it, I hope it works as well as it looks. I guess I will luck up one day and find a nice old beam and clean it up and use it for more constructive purposes. The antenna rotors I had really forgotten about, but that is a good idea.

Subject: [ham-antennas] Re: Looking for Local Old Ham and or CB Aluminum Antennas

I do the same thing. Collect any aluminum antennas I can, with an eye
on making them into ham band antennas.
bear in mind, TV antennas are good for parts, but often not as
durable as commercial and ham antennas. Plus are not cut for any of
the ham bands.
an antenna cut for the old TV channel 2 would need elements made
longer for 6 meters, and the UHF sections are usually too short for 70
centimeters.
some might work on 2 meters, but still might need work.
as for durability, I lost 1/2 an element on the TV antenna I have up.
The plastic broke on one side. I did find the element and put it
aside.
I have a couple of former 11 meter antennas, one I plan to either fix
for 10 meters, or convert to 6 meters. the other is an odd antenna,
horizontal elements, shaped in a "U" shape, made for use on a van
roof. Claimed to be vertically polarized, though I don't see how. It
could convert to 10, or even 6.

I considered making it into a square (like a squalo) for an omni 6 meter. It used a trombone capacitive coupled match, and a fast check with my analyzer shows it to be resonant on 11. making a mount for a squalo will be my challenge, and getting it resonant on 6. the trombone I can modify, having used teh same kind for 2 meters, and having a commercial antenna for 70 Cm that uses a similar type.
really old single band yagis made for TV can be converetd. One for channle 6 could be cut down for 2 meters, one for 2 enlarged for 6, and a channel 13 cut down for 1 1/4 meters (222-225 Mhz).
CB verticals can often be modified for 10, or 12 meters, some even for 20 or 17 meters. also, keep an eye out for working TV antenna rotors.
I used one with a large 10 meter beam years ago, and more recently, for a 4 element 6 meter beam, with a 2 meter beam mounted above it.
I also hope to get my hands on a tower from a TV antenna system, but not holding my breath.
oh yes, some people have been misled to think that their older TV antenna will not work with the new digital TV. LOL....

Yes Allen, the bid process fell in my favor price wise. Sorry I did not have time to talk to you about it during the process, but felt it best to let things go and see what the results might be. As of this Tuesday, due to the Holiday tomorrow, I should have what appears to be a fairly nice Yaesu 301D with speaker/power supply and a tuner. I was lucky enough to trade a few things and spend a small amount of money to get the entire rig plus some things that the operator said he would throw in. Your tuner was sort of a backup just in case, due to negotiations with this fellow for it separately from the rest of the radio. Now it seems I will have two of the tuners, not a bad position to be in if either one fails. I did not know if I would get it, so I just stayed quiet about it. I hope this did not case any misunderstanding or unpleasant feelings, just trying to do the best I could. By the way, is your Yaesu Tuner black, the picture makes it look grey.

Yes, the tuner that I have that you won on EBay is Black.

You got yourself a steal of a deal on that tuner that's for sure, considering the average sold price on those was $181. according to EBay. I had honestly thought about putting a reserve price on it when I relisted it but forgot all about doing that when I relisted it in auction format.

The horizontal u shaped antenna is maybe something like the ddrr antenna
Roof of van form lower half of antenna
It is (to say in easy words) a very short vertical with a big capacity hat
25 vears ago I found a homemade ddrr for 11m ... yes it worked ...
Was abt 1-2 s units down to my 5/8 vertical
But the vertical was at 15m over ground on a pole
And the ddrr was at 8m height in the attic under the roof shingles
So not a fair comparison
Should be easy to tune to 10m (lower the end capacitance)

20104. AW: [ham-antennas] Yaesu 301D Tuner

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-10 10:57:59 UTC
From: Siegfried Jackstien
Topic: 20090 Message: 20104

Hello walt
I have a fc901 tuner
It is almost identical to the 301 (a bit different design on front)
Now here comes the story
In these tuners the band-switch has 3 rotary switches on one axle ...
One of them is used for the coil as band-switch and the 2 other are only
used to bridge the tuner (switch to bypass) ...
On my tuner one of the ceramics wafers were broken :-(
Now here the story how I modded the tuner:
I added a dpdt switch at the backside of the tuner (right over the
swr-bridge was some room)
So that was solution for bridging....
For band-switching I could get a one row rotary switch with lots more
contacts from a friend (15 contacts! Plus one added by me)
I added coil taps between the other original taps
put it the new switch
And clued another dark grey pvc front-plate over the original (only at the
bandswitch area) with new white rub-on numbers on it
Looks great and tuning is much easier with more coil-taps :-)
Additionally I converted the longwire output (antenna position 4) to
balanced output with a homemade balun (lift the ground connection inside and
use both screw-terminals floating!)
It is not in original state anymore now .... but looks original (almost) and
does work a lot better!!
(For tuning a longwire just put it in a coax output with a banana plug)

fine you a old CB antenna and convert it to 6 meters you should be able to fine one around they work very well in 6 meters

just take a 1/4 cb and make it a 1/2 wave on 6

most base cb antenna are 13' bring it down to about 9' and the bottom rails make then about 4.95' and it should have a low SWR's from about 51- about 52.75 maybe a little more try it see how it does

Chameleon V1 Mobile antenna! An excellent Choice!

Guys check out this small video made by YV5OF on his mobile station, he installed a Chameleon V1 antenna on his Mitsubishi Montero and check out some of the results. The antenna seems very promising.

The video:

http://www.youtube.com/watch?v=dMH1WN8xVSA
<http://www.youtube.com/watch?v=dMH1WN8xVSA&feature=player_embedded>
&feature=player_embedded

The company website:
www.chameleonantenna.com

The Antenna is rather simple But more efficient than my ATAS. I have nothing against the ATAS, in fact it proved to be a nice little piece of equipment while I had it but I simply needed a bit more. I would ,like to know any opinions you may have on this system.

73's,

Dario Carrera

20109. RE: [ham-antennas] Re: Portable / Mobile NVIS Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-10 15:58:49 UTC
From: jim burns
Topic: 19957 Message: 20109

Try an Alpha Delta DXDD at around 15 - 20 feet. An ARES group in Ohio just completed a comparison of the DXDD against 9 other NVIS antennas including some specifically designed and built for NVIS. The DXDD "performed flawlessly" (quote) and proved far superior to the other nine antennas. Alpha Delta will be introducing a new version of the DXDD that is NVIS/Portable friendly.

Jim, WB4ILP

Subject: [ham-antennas] Re: Portable / Mobile NVIS Antennas

After a week of experimenting.
Testing is with myself and another station 40 miles away, but over a mountain. We know no ground wave is working. Our end goal is to have reliable, portable low power NVIS comms less than 200 miles.

First we both tried a Hamstick "T" dipole arrangement mounted on a tripod 8 feet high on 40M with no success. No QSO even at 100 watts.

Then we tried 64 ft wire dipoles for 40 meters. At first we had the dipoles at 8 feet high, and heard very faint copy at 100W, and none at 50W. At the same time I was having great qso with people 400 to 1000 miles away, so that told me my radiating lobes were still too shallow.

Then we kept lowering the dipoles until we found a sweet spot for 40 Meters. Look like 3 feet high at the center and 2 feet high at the ends, just supported with wood stakes. Now we have good copy QSO at 5 WATTS SSB! So now we have 40 and 60 meters licked. 80 meters showed no signal- I'm thinking the dipole needs to be 2X higher for 80M.

Now that we have a handle on antenna height, one of us will go back to the Hamstick arrangement, only lower, and try again.

The next step will be trying PSK at less than 5 watts.

I'm looking into other portable NVIS antennas, some are dual autotune screwdrivers, some are just mil-spec loaded coils.

To be continued.

Tom N3UJM

> As soon as I get the stud for my 3/8 x 24 mount Iâ€™ll be doing a 40 / 75 meter NVIS but up at 12 to 15â€™ off the ground. My vehicle will be the ground part of the antenna so should be interesting on how long the wire will be. Iâ€™ve been trying to convince our local SAR (Search and Rescue) group to go NVIS on 40 meters, but of course that would mean more generals and higher licenses. We generally donâ€™t do searchâ€™s after dark. We are always in nasty terrain.

Date: 2011-10-10 17:04:38 UTC
From: Jay Jordan
Topic: 20106 Message: 20110

I've used the V1 (borrowed from a friend) in a portable application and it performed well for me . I did not have an analyzer but my Z-817 tuned it easily. I have since bought a V2L that I use, and I am happy with the results .I substituted the Stainless top whip with a shock corded whip for ease of portability.

From: YY5DCV - Dario Carrera <yy5dcv@...>
Chameleon V1 Mobile antenna! An excellent Choice!

Guys check out this small video made by YV5OF on his mobile station, he installed a Chameleon V1 antenna on his Mitsubishi Montero and check out some of the results. The antenna seems very promising.

See if you can get an old cb halfwave
Throw out the steup-up transformer in the base or if ringo ranger or city star the "coil" that is formed like a ring or oval ...
Now what do we have here?
A nice quarterwave for 20m ...
Add some radials and youre done ...
Ad an autotuner at the base and work 10-20 with it
Or just shorten it to any band above 20 ....
You could even use the 20m quarterwave as "pole" for paralleled wire radiators and make a multibander from it
Just "some" ideas what I made with old cb antennas ...
Makes great fieldday antennas :-)
For using with an autotuner it is better to seek for a 5/8 vertical ...
Because it is longer (6.5-7m) you can use it 10-40m!!

20115. Several Wattmeters and SWR Bridges FS

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-11 15:28:07 UTC
From: Ken Simpson, W8EK
Topic: 20115 Message: 20115

Several Wattmeters and SWR Bridges For Sale:

Swan WM-2000 Wattmeter / SWR Bridge:

The Swan WM-2000 power meter and SWR bridge covers 3.5 to 30 MHz. Power scales are 200, 1000, 2000 watts. It has a very large (over 5 inch) meter, for easy visibility. The rear panel has SO-239 input and output connectors.

This is an extremely nice meter, primarily due to its large physical meter, making it easy to read.

This one is in extremely good condition. It works 100% and looks very close to new.

With paper work for $80.

Autek WM-1 Computing HF Wattmeter:

The WM-1 Meter doesn't make you stare at crossed needles or make adjustments or do any calculations to read SWR. Instead, like magic, it shows SWR instantly and continuously. So it's a snap to do SWR plots, adjust antenna tuners, or just glance at the SWR occasionally to see that it's still low.

This meter has scales of 20, 200, and 2000 watts. It will measure either peak or average power. And peak is true peak, with a slowly decaying display that can really can be read. It also has a separate sensor that can be separated from the actual meter. It covers from 1.5 to 30 MHz, and will cover to 54 MHz at reduced power, so it will cover all of the HF bands, plus 6 meters.

This particular meter works 100% and looks fine. Paper work is included for $100.

Heath HM-2140 A, dual meter Wattmeter / SWR Bridge:

The HM-2140 A uses two separate meters to measure power and SWR (forward and reflected power). It will measure either average power, or peak power (PEP) with a 9 volt battery. Power ranges are 200 and 2000 watts. Frequency range is from 160 thru 10 meters. It has a remote sensor, which permits the meter to be separated from the coax connection by up to 3 feet. This is the "A" model of this meter, which is the Heath Brown color (not the green), and has more features.

More details can be found at
http://www.radiomuseum.org/r/heath_wattmeter_hm_2140a_hm2140.html

This particular unit works fine, and looks very close to new.
With paper work for $100.

Heath SB-634 Station Console, with Wattmeter and more:

The Heathkit SB-634 station console is a multifunction unit.
It contains a 24 hour digital clock (6 large digits, including
seconds), 10 minute interval timer (3 digits -- minutes and
seconds), phone patch and an SWR/Power meter. The large
wattmeter reads either 200 watts or 2000 watts full scale,
in addition to SWR. It matches the Heath SB series of equipment
(Heath green), and is powered by 115 V AC.

This unit works on all of its functions. It looks extremely
nice. I can not find a scratch on it, but there is very slight
(and I emphasize very slight) wear on the 2000 watt push button.

With paper work for $150.

HF and VHF Standing Wave Ratio Bridges:

All of these cover from 3 to 150 MHz, covering HF, 6 meters,
and 2 meters, so are ideal for the new rigs with 6 meters and
2 meters in them. SO-239 connectors.

Carter Craft 90-300 HF SWR Bridge:
The Carter Craft 90-300 is a single Meter SWR Bridge /
Field Strength Meter. It covers from 3 to 150 MHz,
covering HF, 6 meters, and 2 meters, so is ideal for
the new rigs with 6 meters and 2 meters in them.
SO-239 connectors.
Although this has a Carter Craft name on it, it is the
same meter that was sold years ago under a couple dozen
different names, including Vanco, Midland, Quements,
Olson, and many others.
This one works fine, and looks extremely nice. I do not
see any scratches on it, and I am 99% certain it has not
been used, except for my testing of it.
In its original box with original instructions and little
field strength antenna. $30

Quement SWB-2
This unit features two separate meters -- one for reading
forward power and another for reading SWR. This permits one
to easily monitor both the power going out, and the SWR on
the antenna at the same time.
It works fine and looks great. With paper work for $37.

Royce 2-100 Single Meter SWR Bridge / Field Strength Meter
This one works fine, and looks extremely nice. I do not see
any scratches on it, but it does have a previous owners name

on it. In its original box with original instructions. $28

I also have many other accessories available such as many
different types of microphones, HTs, VHF and UHF rigs, HF
and VHF/UHF antennas, etc.
Just too many to list here. Please e-mail your requests.

Prices do not include shipping from Florida.

Thanks.

Ok ringo ranger style ... with a slider that goes to center of coax ....

Throw away the ring and the slider (keep washer, nut etc.)
Now you should have a horizontal plate were the connector of the coax is in
and another plate that is connected to radiator with 2 holes on its ends ...
right?!?
Bent the upper flat in a u-shape (downwards) that the hole matches the
center of the coax connector... attach nut and washer back to the coax
center
Ready (almost)
The unused hole in the lower plate (were the lowest end of the ring was
attached) could be used to connect the radials
That□s it :-)

20119. Re: Portable / Mobile NVIS Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-11 20:58:34 UTC
From: Tom
Topic: 19957 Message: 20119

Using my 2 foot high 40 meter dipole was a success in the PA QSO Party this past weekend. I came to the contest late, not knowing it was on, and in one day logged 55 out of 67 counties with 5-9 reports. So I know I can pretty much cover the tri-state area. Now I have added another identical dipole crossways and feed it with a 90 degree delay coil and switchbox to go circular polarized to capture both ORD and Ext ORD waves. There is a noticeable improvement.

Ok ringo ranger style ... with a slider that goes to center of coax ....

Throw away the ring and the slider (keep washer, nut etc.)
Now you should have a horizontal plate were the connector of the coax is in
and another plate that is connected to radiator with 2 holes on its ends ...
right?!?
Bent the upper flat in a u-shape (downwards) that the hole matches the
center of the coax connector... attach nut and washer back to the coax
center
Ready (almost)
The unused hole in the lower plate (were the lowest end of the ring was
attached) could be used to connect the radials
That□s it :-)

20121. Another question on insulated copper for wire antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-11 23:45:55 UTC
From: pchapman920
Topic: 20121 Message: 20121

Trying to spot a new antenna or adding a leg maybe for 75 on an existing 40 dipole. Either way, for 75, I will have to go literally through a tree or two and would have to most likely rub branches or leaves. I have no doubt you folks would give a thumbs down on bare copper for this one, but what would be your opinions of using stranded insulated, assuming I am very careful of sealing the cut ends etc. I bought some odd lots of dacron rope dirt cheap and would not have considered before now as the rope span would be quite long, but would have a tree that about 10 feet of one leg would have to pass through, and it will touch.

20122. RE: [ham-antennas] Another question on insulated copper for wire antenna

Topic: 20121 Message: 20122

Just a quick note about rope length , I don't consider 100 or 150ft of rope long, it all depends where you tree or support is. I have a 135ft doublet and one end has no tree so it is run out about with 150ft of rope and makes sort of a half inverted V on one end, the other side runs out to a 2x4 up on the top of the barn so I guess it is verted. Going thru a tree should be no problem on 74 & 40 HF unless you operate during a heavy rain.

Thanks for the response Rich:

Let me clarify a bit. I would not have considered but picked up a bunch of uv dacron 1/4 inch under 10 cents a foot. Now i can look at what at what i would not have considered before, now no longer a matter of having to string it a long way, and also clarify I DO want to operate during a heavy rain and assume all conditions. If I add to a free and clear 40 meter dipole, maybe that is not good. Appreciate however as I look for opinions of running single or multi dipole with trees and limbs in the way but using insulated antenna wire, along with bare copper in the free and clear areas.

I don't know for sure what the action of rain and your antenna will have. I do know my ladder line fed 135 doublet is more sensitive to rain than my coax fed loop. How about a small line with a $2 plastic close line pulley from Lowes tossed over the very top of the tree and a small line thru the pulley to support the antenna, with luck it will keep the antenna clear 98% of the time if the wind stays under 27MPH.

Adding to a 40M dipole should be no problem I ran a 75,40,20,17 & 10 dipole on one coax for a while.

Ken,

I am definitely interested in the WM-1 meter, Can you tell me the following regarding this unit:

1) are you including the external power supply with it ?
2) is this the version with the lighted meters ?
3) are the meters white face or black face (there have been both types)
4) does your price include shipping, etc ?

Thanks very much and 73,

20126. Using the Butternut STR-II stub tuned raidial system on a Hy-Gain 18AVT/WB-A

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-12 12:27:56 UTC
From: Military1
Topic: 20126 Message: 20126

This antenna is roof mounted about 25' up (two stories above ground). Current radial system was five wire rotor cable, four sets (2 wires on 40, 1 each on 20, 15, and 10M in each set). Need to replace radial system due to age. Would like to do so with minimum wires (local family restriction). Found a write up on a clone of a Butternut STR-II system in another forum.
http://www.eham.net/ehamforum/smf/index.php/topic,59947.0.html Can I use this lay out with satisfactory results or can I take the recommended Hy-Gain radial dimensions (37" for 40M, 18' 7.5" for 20M, 11' 10.5" for 15M and 9' 10" for 10M) and some how come up with a stub tuned elevated radial set for the Hy-Gain using twin lead 300 ohm wire. My goal like the STR-II would be a total of four radials. Is the 300 ohm key or would some other open wire work better, I.E. ladder wire. Thanks for any comments and advice.

The insulated wire will work fine . my 75/80 metre runs through and touches a limb . just remember that the insulation will make the antenna seem electrically longer so you may have to shorten the ends a little more than the calculations show . I had to do that with all 3 dipoles .

Thank you mucho Andrew. The voice of experience is always appreciated. I remember the elongation of the copper with insulation during my more "not very bright, but lucky days" of ham radio I had boxes of insulated number 10 at my disposal and was frustrated with crap rope that rotted back in the 60's, so I not only built a multiple band dipole with insulated #10, I used it for rope as well. Worked great, but looking back, I really do no think it was very smart to attach a lighting rod to my antenna on the other side of the insulator and tie it to a tree....dumb but got away with it...copper was cheap once upon a time before the EPA and China.

Copper tubing for plumbing is now almost 500% of what it was a bit over ten years ago, stranded plated bare copper wire about 300% over seven years ago.....insane....thank you government regulation!!!

Will go that route as there is a November Stone Mountain coming up with Wireman and will buy a few hundred feet of insulated strand, just for future proofing.

I am ignorant about operating with trees in the equation never having lived where trees were available to tie to or to run the wire through, (Arizona 1952 to Mar 2011)
Question: IF you are using insulated wire how will the tree affect operation other than the water on the leaves de-tuning the antenna?
Is that all it will do or is there something else to look out for?
Hope you can set me straight on this.

Hi Rich.

I've lived in a tree full area and have used them for support my entire life. To install my Carolina Windom 160 I used a slingshot to shoot a line over the top of (2) 50' oak trees and pulled 1/8" black Dacron support line and pulled the antenna up. I use 12 ga. Insulated, Stranded Wire (from Lowes in 500' rolls) and the short leg is in the clear but the long leg goes 15 - 20 ft. over the tree and I see no real issues with my SWR even in the rain. I keep my power as low as needed but use up to 1kw. without problems. I leave a slight droop in the antenna for tree movement in the wind and for big storms I'll slack up the antenna with plenty of droop for the trees to blow around. My Carolina Windom's are both supported in the center by another line over another branch and I can lower the entire antenna to the ground when needed to work on it. I have friends who use bare wire and they tell me it also works fine but I never tried it since my insulated wire has worked so good.

73,
Tom, KE1JF

From: Richard Schmuke
Topic: 20121 Message: 20131

Very good information Tom but it was Adrian that had the question. Being from Missouri I have always been around trees. I use a fishing rod to put my first line thru the oak trees.

Now for Adrian’s question about de-tuning. As the frequency increases the antennas become more sensitive to trees. A 80M dipole will have very little reaction but a 2M beam will not work as well to a sap filled tree full of leaves as clear sky.

Now a question for Tom, as you loosing you black oaks. My whites are doing fine but my blacks and reds (still in the black family) are dying.

Rich ,KDØZZ , ☺

from the middle of Missouri , out in the sticks with the hicks and the ticks.

Please note that the voltage at the ends of a dipole (specifically, 1/4 wl away from the feedpoint) will be high. High is a relative term, but a couple hundred volts would not be suprising from a 100W transmitter.

THHN insulated wire is rated for 600V. Running QRO would put a few thousand volts at the peak segments, and that *will* arc over to a tree.

agree on the price of copper now . I had to replace the dipoles a few years ago and instead of the copper wire I got 1/16" galvanize lift cable and it's hardware . the 1/16 cable is 8 cents a foot here and the u bolts are not expensive either . I got the wire and all the hardware for under 15 dollars . 110 feet of cable. the only problem I have had with it is that I had to take it down once and clean the connections to the 450 ohm line . cleaned it and put some antiox grease on the connections and taped them , no more problems yet . as far as I am concerned it works as well as a copper dipole and has a major advantage , after it has been up awhile it turns a dull grey colour and is almost invisible . great if you are in an area with HOA's . the rope is not much better now unless you live near water where there is a marine supplier . then you can get the good double braid dacron rope . the rope from tractor supply will last about 1 year if I am lucky . how did you get # 10 to stay up ? as a retired electronic tech I had lots of # 12 THNN and made the 75/80 metre dipole from it and it is hard to keep it from sagging .

I have a g5rv up 35 feet one end in a tree and the other end to my tower,the end at the tree has about 100 foot of rope so that i can get the latter line feed right at the window of my radio room so to have the feed line short .
Because of this i had sag in the middle. so i got a small tripod and a fiberglass pole on my roof ,the top of the pole is a whip and moves freely with the wind. so now
the latter line is completely vertical and no more sag. i have worked the world on this antenna at very little cost.
the wind blows hard here and this has been up for many years without any problems.

Since I had trees in just the right places, I was able to use a cross pattern on the wire, so instead of two supports, I had four which eliminated most of the sag, leaving some on purpose for wind stress. Center support was a balun which even thirty years ago was only a few dollars more than a vanilla center support. Both bands were under 1.5 to 1 at most any point on the General Class band. (SOOOOO glad I finally got around to upgrading my license. Knocked it out in 2 weeks with the free Ham Academy drill software.)

My first long wire antenna was supported at one end by a rope that ran through a pulley and down to a cement block. That was in 1966. I currently have a 102-ft doublet that uses a pulley support. The counter weight is a tree branch. It swings a bit in the wind, but it blends in with the trees very well.

I have been sitting here laughing my butt off after reading this. I researched strain (wind relief) contraptions a while back.

Some that I saw were:

1. Garage door springs....pricey and they rust.

2. Bungees.....they rot

3. Shock absorbers....pretty dumb....they work in one direction only.

4. Nothing.....better than the above three.

5. A bucket of rocks.....sheer genius

6. A modified bucket of rocks....Fill it with Peat and lightweight potting soil and plant tomatoes in it.

Brilliant Idea, thanks for passing that along.

I must be using some sort of indestructo materials.

I have up about 40 feet a loop that is 600 feet long, made from
alunimum electric fence wire. insulators at the four corners, and ropes
that were shot with a bow and arrow over the top of the trees and then
pulled down to a low branch to tie off to.

no weights, no springs, no pulleys. nothing, it's been up for three
years now.

What kind of rope? Nylon?
Many ropes are like bungee cords in this application. (especially long ones)
If you don't keep the antenna tight and you allow the wind to blow it about, it's tuning can be
changed by it's position.

If the antenna is kept tight without some kind of "rubber" strong winds will break something.
I have always used a pulley and a half or whole concrete block. I use and recommend Dacron cordage.

20142. Re: [ham-antennas] Another question on insulated copper for wire antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-13 23:26:12 UTC
From: roger.h@comcast.net
Topic: 20121 Message: 20142

Using wire for 41 yrs as ham. Some ant better than others. I run it where I have to. Does the tree or folige interfere with ur signal. It does a little. I don't pay attention to that. I am a firm beliver in hearing the other station so you can work him or her. If no wire you can't hear him to well. Hi Hi. I try to always use insulated stranded wire of the right AWG (guage). My personal rule is I don 't like Tuners, but I use them if I have to. I try to get the ant as resonate as I can. This brings your reactance to zero and no Standing Wave, (SWR) This not always possible. Just make the ant resonate and cut your losses. A tuner causes losses but in turn fools the back of the rig into believing the ant is perfect at 50 ohm impedance.But in reality from the back of the radio dow n the coax to to ant including the wire ant has probably 3:1 or worst SWR. There a many hams who have a ATU in their radio and another Auto tuner they bought to help. I say keep it simple. Get the most out of your ant, build it right and put up right and use forever. I use Cable TV hardline to 2 of my towers for the triband and 40 meter beams. They give it away. I make my own connectors from copper pipe and screw clamps. It works great and very low loss.

I use 450 ohm and 300 ohm flat ladder for lower loss as one of my towers is 227 feet from the shack. I have a Ameritron RVS-4 remote coax switch about 100 feet from shack to tower and pick up another 3 wire antennas. I'm on disibility as had a Heart Transplant but I manage. I can scrounge with the best of them. Their is so much info on the internet esp on antennas. Just practical info. Save mon ey like me. I also want to say this without offending anyone on here. Be careful on the advice you give to other hams. I have read some threads on here recently where some of the answers or advice was not even correct. I only joined about a month. Just be careful. I have taken 6 good lightning surges from close by hits and they eat m y station up like eaten dollar bills. I've learned my lessons well. When I shut the station down at night or any tim e I disconnect power from wall, disconnect router from Cable Internet, disconnect all coax and I remove the station ground from all equipment. Yes, I float my station. I'll get hatemail on that last disconnect. Hi Hi. Yes I said it. I'm tired of replaceing damaged equipment in my station. You do what you please. Anyway I can take. I love everybody esp the women hams. Thanks Roger, 73, W4IV, ARRL Cert, Instr, VE and VE liason

Subject: Re: [ham-antennas] Another question on insulated copper for wire antenna

I am ignorant about operating with trees in the equation never having lived
where trees were available to tie to or to run the wire through, (Arizona
1952 to Mar 2011)
Question: IF you are using insulated wire how will the tree affect operation
other than the water on the leaves de-tuning the antenna?
Is that all it will do or is there something else to look out for?
Hope you can set me straight on this.

20143. Help with sick mosley ta-33

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-13 23:30:32 UTC
From: anthony
Topic: 20143 Message: 20143

Im having a problem on 20 meters only with this antenna. When i run 100 watts my swr is around 1.3:1 on 20 meters with no problems. However when i fire the al-80b up and run power (800 watts) i tune it through my palstar 1500cv down to 1.1:1 but out of nowhere it jumps up to like 8.1 or higher. Im thinking one of the 20 meter traps is screwy. Im not even sure if this antenna has 20 meter traps. Any help or suggestions would be apreciated. thanks guys.

The traps on that antenna act as loading coils for 20 meters thats why
the elements are not full sized.

What does it do without the tuner? I never ever used a tuner on my TA-33..

One thing that comes to mind is that any balun or other device with ferrites may only be rated
for ~200 Watts and is being saturated by such higher power.

up until the above, I was thinking that the tripod/mast was going to support the weight of the Centerpoint, lifting it to a horizontal line, parallel to the ground. then he said "flexible whip" ????? wt??? how does the flexible whip interface with the sagging dipole/centerpoint/ladder line feed point????

very confused...

From: Dave Hunter
Topic: 20153 Message: 20153

Hi Folks:

In order to get your rope around your wife's neck, to counterbalance a sagging dipole, you need to get the end of the dipole up in the tree in the first place.

Some use bows and arrows, some use slingshots - years ago, when we were contesting we relied on a fellow who was a pretty good shot with a Bow and Arrow.

But THERE IS A BETTER WAY! It is called a CABLECASTER. It is dart shooting gun by Greenlee (remember the punches?)

It is a gun designed to shoot darts with monofilament line tied to them in order to shoot line over a tree.

See:
http://www.youtube.com/watch?v=ElOD62_NgOc

And:
http://cableorganizer.com/greenlee/cablecaster/

Another version with up to 150 foot range - Laserline Pull String Shooter:

http://www.youtube.com/watch?v=dyU-5fh1BVw&feature=related

And:
http://cableorganizer.com/laserline/

Ahhh, progress!

Well i used a poor choice of words the whip is not part of the antenna , it is the top part of the fiberglass pole and is very flexable but stiff enought to hold up the centerpoint at the feedline.

suspect that a garage door spring would be too strong as well as too heavy . a screen door closing spring would work but unless one lives in a desert climate it will quickly rust . tried that .

A slingshot, a zebco, a couple zip ties, and a 1oz fishing sinker will only set you back $25

The cablecaster and laserline basically only look like more expensive ways of doing the same thing.

20158. RF InShack with 160m loop fed with ladderline need help

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-16 01:15:45 UTC
From: Don
Topic: 20158 Message: 20158

I have built a 160m loop and am feeding it with ladder line.

The ladder line comes in directly thru the window and is connected to my MFJ 962d tuner balanced line. I can tune the antenna with no significant issues at all for SWR.

The rest of the set up is a K3 to an SGC powercube. Power is provided by batteries.

The problem that I am having is I am getting a significant amount of RF problems with a highly distorted TX when I use the loop.

Now there is another thing that needs to be stated about the installation. The loop runs around the house so that the shack is basically in the center of the circle. Also I have a dipole that is close to the loop as well. So I don't know if the RF is coming in thru the dipole. Note if I TX with the dipole there is still RF on my signal but highly reduced. If I disconnect the ladder line from the tuner the RF goes away. (Maybe a tuner problem???)

Right now to be able to use the radio at all I had to remove the ladder line from the shack and I have coiled it up outside at the feed point.

So can this installation be salvaged, as I am thinking my number 1 problem is that I am in the center of the loop. Second I am starting to think from reading on the internet that ladder line should not be run in the shack as any RF can not be choked. Thus I should be using a 1:1 current balun outside of the shack and then run coax between the tuner and balun and I would suspect put some ferrites on the coax.

Anyone who can provide help in figuring out this problem that I am having your feedback will be appreciated.

Thanks
Don

Well, after seeing some of the really great ideas and inventions, I proceeded to go on eBay and bid on two items no one seemed to be interested in. Just my luck, I was correct. I have a 50 lb. crossbow pistol with arrows and an el cheapo casting reel, for a grand total of $18.00 with shipping. Due to health issues I have not given the combo that I put together a test run yet (cellulitis in my leg). But I can't see why this will not work. My only question now is how far will it shoot a line. But I am hopeful!

It sounds to me like you need to work on the grounding, especially the tuner needs the largest strap you can find with the shortest length you can run to the most and deepest ground rods you can get in.

A bungee cord, or 2 in series, or 2 in parallel also can do this well depending if you want strength or lots of slack movement. In my QTH we have trees but heavy winds so sometimes I create a "fuse" - I pull the pulleys to get the diopole tighta nd then connect one end rope via a short thin wire (i.e. smaller than the antenna wire) so if there's too much strain, that link will releases before the dipole will, and introduces 3' of slack. Seems to work well.

20163. 40 Meter Loop Balun Placement

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-16 12:09:48 UTC
From: ke1jf
Topic: 20163 Message: 20163

I helped a friend put up his 40 meter loop and he has a 4:1 balun in the center at the top and it is working great for him with low noise. Would it affect it's performance if I put one up with the balun at one of the bottom corners ? It would be easier to maintain and would require a shorter coax run. Just wondering what effect moving the balun would have, my main interest is for DXing.

Tnx in Advance !!
73,
Tom, KE1JF

20164. Re: [ham-antennas] Hygain Rotator.

Yahoo group: ham-antennas (2011-08 — 2011-12)

From: doug pfaff
Topic: 19122 Message: 20164

Hi

Check the bolts that secure the beam to the mast, and mast and rotator clamp assembly.

Turn rotator to north for 0 then swing beam to north re-tighten the bolts,with correct voltages at 0,180,and 360 I would not suspect the electronics,

Its the mechanical alignment of the physical beam and rotator also check the bolts on the rotator clamp, the bolts have likely loosened over the years .

Take up new clamps and bolts nuts etc to avoid too many trips up the tower

Subject: [ham-antennas] Hygain Rotator.

Hi Group,I have a Hygain HDR300AX which is not reading direction correctly.

When it reads 0 degrees the antenna is pointing north, as the antenna
is rotated the display reads correctly until 140 degrees and then jumps
to 574 degrees and from that point on the display does not change
although the antenna continues to turn ok.

My thoughts are that the 3 turn pot has gone faulty somehow,
although the voltage readings are correct as given in the handbook
for 0,180 and 360 degrees so i wonder if anyone has had any problems
with the controller or any similar symptoms with these rotators?

I would be grateful for any info,Thank you,Mick,MI0GRG.

Bob

We have seen this exact CATV issue due to poor maintenance by the cable operator where ham band vhf gets into a system,causes can be poor installation of connectors in customer premises and problems in the cable operators overhead distribution plant and leaky line amplifier boxes.shield breaches etc

watch out for newer BPLWtc(broadband over powerline etc)

A good reference is ARRL RF interference handbook also refer to the cable channel allocations in FCC the allocations also have a UHF component.

Also remember that the WRC every 4 years reviews worldwide assignments agreed to internationally for all radio and other services satellite etc

Bob, That’s rather interesting as I’ve never heard of “anybody” having TVI issues after they’ve gotten cable be it analog or digital. I had issues in the past with TVI but they involved outdoor antennas but never with cable

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Stealth Radio & TVI?

I live in a retirement complex where there is no way to have an outdoor antenna. But at least I am on the 4th floor.

I have a decent 40M dipole 6" below the ceiling. It does a decent job of receiving on 40M and higher.

I have used it on 40M with my DX-60, both CW & AM.

Until about three years ago we had analog cable. But then Comcast switched us to digital.

The DX-60 only produce minor TVI on the analog cable. But digital cable is another problem.

The fundamental problem is RF overload. I have ferrite chokes to put on the cables but I have not done it yet. I hope to try them this week.

My question is: Has anyone had a similar digital cable TVI problem.

That depends on the size of the loop. The important thing is: where the high current is on the
loop, for a dipole the high current is surrounding the center of the dipole. (when feed on end or in
the center)
When the high current is at the highest part of the antenna your signal will be a bit better (at the
other end of the circuit) than if it is lower, one good reason to keep your doublet from sagging in
the center.

Tom

Can you elabrate more where did the strange design come from using the 4:1 balun?

The design I had was out of the ARRL Antenna Compandium Handbook

I used the standard 1/4 matching coax method OF 75 OHM TV COAX and got 1.5 swr across the whole band.

The loop impedance is about 100 ohms so why was the 4:1 balun used, this would give a 25 ohm factor and still 2:1 for the transmitter where was the design found with the balun?

If you're primarily interested in DX I feel feeding the vertical loop either on one of the vertical sides or at one of the corners will provide the vertical polarization needed for a lower angle of radiation. I am about to put up a similar antenna and I am hopeful it will perform well on all bands 40M and above when fed with open wire line and using a tuner.

If you are an ARRL member look up an article in their archives named Transmitting Loops Revisited by Doug DeMaw from March 1988 QST for more information.

Subject: [ham-antennas] 40 Meter Loop Balun Placement

I helped a friend put up his 40 meter loop and he has a 4:1 balun in the center at the top and it is working great for him with low noise. Would it affect it's performance if I put one up with the balun at one of the bottom corners ? It would be easier to maintain and would require a shorter coax run. Just wondering what effect moving the balun would have, my main interest is for DXing.

Tnx in Advance !!

> of the spring and use that for a tension device when hooked to a tree
> allows for the wind sway

I THINK that makes more sense... I am assuming the tube with cap is dropped down over the top of the screen spring and the tube acts like a shock absorber cover??? good idea. why didn't I think of that and pretty much save the Rustoleum and spray it with a metal preservative oil which is a lot cheaper!! drilling a hole across the cap on the side would allow the spring top to be captured by a piece of wire (we call it baling wire, down here) would keep rain out of the top of the tube. hmmmm thanks again.

Still not sure how that mast connects with the feedpoint though.<G>

Sure Doug,

He told me he used 1005/freq = total length. Then he placed the 4:1 balun at the top and supported. He added 2 insulators giving it 3 equal sides with the bottom level with the ground about 15' high. It's more like a triangle than a square or loop but it performs great with roughly 1.2:1 across the CW portion only needing a tuner up over 7150 and the rig tunes it fine. Perhaps a loop is not the correct name but that's what he called it.

Tom

Can you elabrate more where did the strange design come from using the 4:1 balun?

The design I had was out of the ARRL Antenna Compandium Handbook

I used the standard 1/4 matching coax method OF 75 OHM TV COAX and got 1.5 swr across the whole band.

The loop impedance is about 100 ohms so why was the 4:1 balun used, this would give a 25 ohm factor and still 2:1 for the transmitter where was the design found with the balun?

I agree with that. However, just a ground rod should provide a good DC path but might not be effective for stray RF. If possible, I'd also run a counterpoise around the house foundation, as well. Use copper wire and connect it to the common ground.

in the center of the loop. Second I am starting to think from reading on the internet that ladder line should not be run in the shack as any RF can not be choked. Thus I should be using a 1:1 current balun outside of the shack and then run coax between the tuner and balun and I would suspect put some ferrites on the coax.

Sometimes goofy RF in the wrong places problems are caused by a bad shield connection in a coax
connector, best tested by substitution when possible.

Feeding it at a lower edge (or a bit up from that ... best would be 0.25 wl
from top so abt 2.5-3m out of the lower corner) would give you vertical
polarized low angle radiation
Feeding it at the top (or bottom center) would give you horizontal polarized
radiation with a higher elevation angle ... but all that depends on height
over ground ... if you can erect it HIGH than horizontal polarization is
better .... but most hams can not get the loop half a wave length high ...
So in that case feeding it vertical polarized is better

Why a 4:1 balun? the 1005/7.150 formular is what I use. A full wave loop normally is 100 ohm impedance. Feeding it at the corner is the best place but should be feed in the vicinity of a quarter wave of the freq set for, but height and type does play ibto it. My loop is a triangle and feed at the corner. Works great. I just have a direct feed to 450 ohm for 157 feet to 4:1 down to RG213 for 131 feet. The best loop I've ev er had especially in fall and winter. Am out now burying 2 runs of Cable TV 5/8" hardline and 1 run of LMR400 for 227'. This is kicking my +%#& and my (87&$@&). Not even considering what it's doing to my &%4(^Fyt$%. Boy I feel better now. 73, Roger, w4iv.

It sounds to me like you need to work on the grounding, especially the tuner needs the largest strap you can find with the shortest length you can run to the most and deepest ground rods you can get in.

If ertical fed and low over ground you have very often close to 50 ohms ...
so a 1:1 would work better on the fundamental ...
On harmonics the impedance goes up so there the higher ratio balun is better
... it depends on height ... and bands of use ... and feedingpoint

Topic: 20153 Message: 20185

The only problem with using fishing line for a messenger line, is trying to pull it over a shingled roof without getting it caught in the shingle tabs...forget it.

I ended up using a 30-foot paint roller extension to get my wire deployed...took all of about 20 minutes.

73, Brian KA9EGW

A slingshot, a zebco, a couple zip ties, and a 1oz fishing sinker will only set you back $25

The cablecaster and laserline basically only look like more expensive ways of doing the same thing.

The Marksman 3060 and 3061 at WallyWorld ($9.99) and other sources is the best for homebrew with the long wrist support and long adjustable yolk....add a Zebco 202...$7.99. I prefer half ounce sinkers....and I add a few inches of pink Mason twine to spot it after the launch.

Just remember safety with a slingshot doing this....the entire payload must go in the pouch if using sinker, pink twine, and if you are using a swivel hook....If you do not follow this rule, you will have limited range and or backfire.....safety glasses!!!!OK????

Considering that the Marksman 3060/3061 has a 200 yard range at full power, this could result in serious damage to your body. Be careful, contain the full payload in the pouch and protect yourself. Hold the slingshot at full arm extension. a busted band could hurt your arm, but better than losing an eyeball.

If you live in one of the enlightened rust belt nanny states like NY, safety is guaranteed by preventing Walmart from selling slingshots.

I ended up buying an EZ-Hang as an impulse purchase at Dayton a few years ago. A lot of money for a tool I'll only use a few times in my life. It does work, though.

20190. Feeding an End Fed Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-20 04:28:10 UTC
From: Gregory
Topic: 20190 Message: 20190

Hi,everyone. I have a question about feeding an end fed antenna. I have one of those end fed antennas that you find on ebay. It uses an unun with 65 feet of wire. Initially, I temporarily hooked it up to a second storey window of my home and strung the wire at a diagonal across the yard. I used a MFJ isolator. Surprisingly, it worked and I made a number of contacts on the digital modes and cw on 20-10. Reception was 1-2 db below my other trap dipole.

My roof is 30 feet high. My window was only 15 feet above the ground. If I place the antenna on my roof I can position it so that about 30 feet of the antenna will be on the roof and the other 35 feet will gradually slope into the yard and can be tied to a tree at about 15 feet high. It does give me all band coverage with a low swr.

Does it matter if the unun is fed from the roof or if the unun is tied to the tree and fed from the lower elevation? I don't think so but I can't find anything on this for sure. I'm leaving it up to the experts on here. Thank you, Greg.

Topic: 20190 Message: 20191

I have the same systemm my unun is mounted near the ground to kee my coax run shorter. The wire from the antenna goes from the unun up to 9ft then from there up to 15ft in a tree. I was told that as long as I don't double back on it that it will work, I run approx 100 watts.

Basically the end fed & unun requires a earth to work against, thats why most layouts you see are as a sloper because the un un is connected to earth stakes or radials.

You can normally place the unun anywhere is best for you as long as the radials/counterpoise is connected and you don't double back the radiator too much on itself.
Try inv L , slopers or even a U or V or unpside down U/CV fed in one corner with the centre up as high as possible.
the main thing with any aerial is to try to make sure as much as possible is as high & in the clear.

Thanks

But what if the end fed antenna is a HALF wavelength long or a multiple thereof? Can't you do away with the elaborate radial/ counterpoise system and simply run the braid side of the coax to an earth ground? There are some very successful commercial end fed half wave antennas that require only the most basic ground connection.

Thanks,

Bob W1RAM

With a half wavelength you will need a matching network as the impedence will be a few thousand ohms. You lose the ability to run much power due to the very high voltage the matching network will be subject to. Evan 100W is likely to cause issues with modestly rated components. And the matching network is likely to render the antenna a monobander.

Unless there is a compelling reason to feed the antenna at the end (e.g., portable operation), most people would be better off configuring that half wavelength wire as a dipole.

Or use a counterpoise of some sort...

Going through the local tower ordnance it states the below. What do you all think it means/

(3) Amateur radio. This ordinance shall not govern the installation of any tower or antenna support structure that is owned and/or operated by a federally licensed amateur radio operator, that is less than 75 feet in height and is placed at a distance equal to or more than one and one-half the height of the tower from any adjacent property line.

Looks like it means it has to be 112.5 feet or more away from anyone else's property while staying just under 75 feet in height. looks like this is applied to the Tower itself, not the antenna. (loophole?).

Joe,

That would appear to mean that if your tower is 50 feet tall, it has to be at least 75 feet from any property line.

If you have a 50 foot wide lot, that would appear to limit the height of your antenna to (50/3)x 2 = approx. 32 feet.

Of course, I could be wrong. But that is what it seems to say.

Sorry about that -- that would be for a lot 100 feet wide. For fifty feet wide, it would be:

(25/3)x2 = approx. 16 feet high

It says that the antenna will be controlled if it is more than 2/3 the distance from a boundry line. If the lot is 50 feet wide, the tower can only be 2/3 of 25 feet. And then it must be placed at the point that is 25 feet from any boundry line.

What it means is that as long as your tower is less than 75 feet in height and within one and a half times its height from any property line, the local ordnance doesn't pertain, only the federal regulations do. You might ask a lawyer (which I'm not) but based on what I've read, and what my lawyer told me, there are court decisions that have ruled that local ordnance can't unduly restrict federally-licensed operation.

So as long as you are within those guidelines, you are OK. You may still need a permit to erect your tower, but the local ordnance doesn't govern height or placement.

I am no Lawyer, but it sounds like the tower height (including antennas) is limited to
a height of less than 75 feet. And must have a 50% clearance factor over the height
of the tower. I read that to mean a 60' tower must be located at least 90' from the
nearest property line.
You know, these towers can jump quite far.

Sounds like an ordinance to keep folks on 100' X 100' lots from having anything useful
for a tower.

20203. Antenna related items FS

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-21 22:37:27 UTC
From: Ken Simpson, W8EK
Topic: 20203 Message: 20203

Antenna related items For Sale:
Coaxial Antenna Switches, SWR Bridges and Wattmeters,
VHF and UHF Mobile Antennas and Mounts, Coax Connectors
and Adapters, Rubber Duck HT Antennas, etc.

MFJ "Strip Line" Coaxial antenna switches:

Both of these antenna switches are in a heavy diecast housing
that utilizes "stripline" construction to keep the impedance
very close to 50 ohms. This means it permits good operation
at higher frequencies up to 500 MHz, and gives over 50 db
isolation. Unused antennas are grounded, with an additional
position to ground all antennas. SO-239 connectors.

MFJ 1704 Coax Switch
Will switch up to 4 antennas. Lightning protection is built
in. It works fine and looks close to new. $55

MFJ 1702 B Coax Switch
Switches 2 antennas. This one works 100% and looks great
also. $24

HF and VHF SWR Bridges For Sale:

All of these cover from 3 to 150 MHz, covering HF, 6 meters,
and 2 meters, so are ideal for the new rigs with 6 meters and
2 meters in them. SO-239 connectors.

Quement SWB-2
This unit features two separate meters -- one for reading
forward power and another for reading SWR. This permits one
to easily monitor both the power going out, and the SWR on
the antenna at the same time.
It works fine and looks great. With paper work for $37.

Carter Craft 90-300 HF SWR Bridge
The Carter Craft 90-300 is a single Meter SWR Bridge /
Field Strength Meter.
Although this has a Carter Craft name on it, it is the
same meter that was sold years ago under a couple dozen
different names, including Vanco, Midland, Quements,
Olson, and many others.
This one works fine, and looks extremely nice. I do not
see any scratches on it, and I am 99% certain it has not
been used, except for my testing of it.
In its original box with original instructions and little
field strength antenna. $30

Royce 2-100 Single Meter SWR Bridge / Field Strength Meter
This one works fine, and looks extremely nice. I do not see
any scratches on it, but it does have a previous owners name
on it. In its original box with original instructions. $28

Heath SB-634 Station Console w/ Wattmeter:

The Heathkit SB-634 station console is a multifunction unit.
It contains a 24 hour digital clock (6 large digits, including
seconds), 10 minute interval timer (3 digits -- minutes and
seconds), phone patch and an SWR/Power meter. The large
wattmeter reads either 200 watts or 2000 watts full scale,
in addition to SWR. It matches the Heath SB series of equipment
(Heath green), and is powered by 115 V AC.

This unit works on all of its functions. It looks extremely
nice. I can not find a scratch on it, but there is very slight
(and I emphasize very slight) wear on the 2000 watt push button.

With paper work for $150.

Heath HM-2140 A, dual meter Wattmeter / SWR Bridge:

The HM-2140 A uses two separate meters to measure power and
SWR (forward and reflected power). It will measure either
average power, or peak power (PEP) with a 9 volt battery.
Power ranges are 200 and 2000 watts. Frequency range is
from 160 thru 10 meters. It has a remote sensor, which
permits the meter to be separated from the coax connection
by up to 3 feet. This is the "A" model of this meter, which
is the Heath Brown color (not the green), and has more features.

More details can be found at
http://www.radiomuseum.org/r/heath_wattmeter_hm_2140a_hm2140.html

This particular unit works fine, and looks very close to new.
With paper work for $100.

Larsen NLA Type Mobile Antennas:

These antennas fit the Larsen NLA mobile mount, which is
a special mount made by Larsen.

Larsen NLA-150, 2 meter antenna, for Larsen NLA mount
Has about 3 db gain on 2 meters.
Coil only, without whip (whip is hard to ship). $10
With four foot whip. $19

Larsen NLA-450 coil and "stacked" whip for 440 MHz
Fits the Larsen NLA mount, and has about 5 db gain on
the 70 cm band. Coil and stacked whip are included. $12

UHF (440 MHz) Mobile Antennas :

Avanti "On Glass" antenna for 440 MHz:
This antenna was made by Avanti to mount on a windshield, or other glass. It does not require a ground plane, as it is a 1/2 wave antenna, rated to have 3 db gain. It is ideal for places where a ground plane is not available, such as a boat or motor home, in addition to cars. A special tuning box is included to match to your particular situation.
Avanti Antenna for 440 MHz
Still in its original tube, unopened. $33

Larsen NLA-450 coil and "stacked" whip for 440 MHz
Fits the Larsen NLA mount, and has about 5 db gain on the 70 cm band. Stacked whip is included. $12

Mobile Antenna Mounts:

Large, heavy duty magnetic mount
This large mag mount will take any antenna with a standard 3/8 inch 24 thread connector. It is very heavy duty, about 5 inches in diameter, with a long coax for $25.

Larsen NMO "Button" Mount
This mount fits into a 3/4 inch hole, and will then take any of the many NMO types of antennas. Coax included.
It is in close to new condition. $15

Coax connectors and adapters:

Prices are per connector. Several of each are available.
It looks like these have not been used.

"N" Connector - Double Male $8

BNC male for coax cable
standard type $2
crimp on type $3

Chassis mount BNC female
square mount (uses 4 screws) $3
screw in type $3

BNC "T" - two female and one male $3

Antenna adapter to fit the BNC connector on the HT and provide an SO-239 connector that will permit a PL-259 to be attached. (BNC male to UHF female) $5

UHF Male (PL-259) to BNC female (opposite of above) $5

UHF double female "Barrel connector" (two SO-239 together) $3

UHF "Bulkhead Connector" - Double female, as above, but for mounting thru a window, siding, etc. about 3 inches long $6

UHF double male connector (two PL-259's together) $3

UHF "T" connector with two female (SO-239) and one male
(PL-259) connection $5

Rubber Duck antennas for your HT:
All are for 2 meters, are in good condition,
and are $10 each, unless stated otherwise.

BNC - Standard length, about 7 inches long
BNC - Original from Kenwood TH-215, about 5 inches long
BNC - Stubby about 4.5 inches long

5/16 inch threaded, as used by Motorola and others
Stubby - 4 inches long

Type F connector - 6.5 inches long

PL-259 connector - 6.5 inches long
HyGain 275, still in original packaging

PL-259 connector - Stubby - 4.6 inches long
Centurion, still in original package

Special for Kenwood TH-21 HT threaded connector
Stubby, about 4.5 inches long - $20

BNC Stubby for 440 MHz, 3 inches long

I also have many other accessories available such as many
different types of microphones, HTs, HF, VHF and UHF rigs, HF
and VHF/UHF antennas, and many miscellaneous accessories.
Just too many to list here. Please e-mail your requests.

Prices do not include shipping from Florida.

Thanks.

Topic: 20196 Message: 20204

I think most are correct. What it doesn't say. In most town ordinances concerning fixtures as tower would be, needs a engin eer drawing/report of type and construction. This report and permit request would still have to be approved by city planning and the town counsel. If approved by both for construction, then it's up to you to build. At certain times during the construction the P lanning Dept would send an inspecto r to check your work for com pliance codes and safety. An when finished you have to request the inspecto r to co me back out for a complet ion in spection. I forgot to include the fees for permit/ engineer/construction/inspections. This is in Middle Tn I may be a little off either way. These actions can be different in each state and/or city. I n my county 30 se of Nashville, Tn. you have this stuff to bear for any alteration to a structure as in house/garage etc. Also for addition or alteration of a in-ground pool, above ground plastic pool, any fence any style, 6' by 6' dutch barn or larger. Almost forgot Amatuer tower. So save those Rohn drawings with the m omen t pounds downward pressur e for the engineer to see. You see the abundance of absurdity. Hams have such a kind heart, they even see beauty in metal structures. Unfortunately most other people don't. Things are different every where you go. I am not a lawyer, just a Senior Real Estate home and land Appraiser. 73, Roger, W4IV. Ok ok, I strayed off topic a little bit. so charge me a fee.!

What is considered "useful" ?
My tower is 30 ft high and I work the world.
I have already clean sweeped T32C and have worked VK9CX on several bands.
VK9CX is halfway around the world for me.

Best Regards

Your math leaves a little to yet figure . A 50 ft. wide lot with the tower in the center would be 25 ft from each side . This would make the maximize antenna height appox . 16ft or 2/3 of 25ft. ... Good DX Chuck Wq5B

Joe,

That would appear to mean that if your tower is 50 feet tall, it has to be at least 75 feet from any property line.

If you have a 50 foot wide lot, that would appear to limit the height of your antenna to (50/3)x 2 = approx. 32 feet.

Of course, I could be wrong. But that is what it seems to say.

I'm not a lawyer either, but I can't imagine that's what it means, since that's not what it says. It says that if you meet those requirements, then the local ordnance doesn't apply. If you want to exceed those requirements, then the local ordnance comes into play, and you have to abide by that. I have no idea what requirements might be in that ordnance, but you can avoid it simply by sticking to the 75 foot and set-back limitations.

Joe--As I understand your ordinance, the law does not apply unless the tower exceeds the 75' height and is an amateur radio antenna. It is my belief (and I am no lawyer either) that if you specify the tower to be under 75' (i.e. 70') no inspector is going to climb that tower to measure the true 80' that it is. :)

I am lucky in that I have a similar ordinance, but excludes amateur and CB antennas. No permit required.

Dale K8TS

I seem to agree with everyone so far on this.

Like a 50 foot tower needs to be at least 75 feet from any property
line. or at least this is how i understand it.

Now how the county came up with this is strictly amazing. I have seen
countless towers fall in videos, as well as from Rohn themselves a
letter and video of tower falling and they rarely fall out to a
distance 1/2 their height. most if not all seem to collapse.

And it is against all common sense that it can fall a distance that is
longer then it is itself. like it can jump out 1.5 times it's own
height. Thats Crazy!

From: Bryan
Topic: 20190 Message: 20213

I drive my half wavelength 20m vertical (http://www.tinyurl.com/wa7prc-vertical20m) with my SB-220. Components are chosen for the power (around 1KW). Assuming radiator Z = 2Kohm...

E = SQRT (P X Z) = 1414 Vrms = 2000 Vpk

My variable C has plate spacing that will handle > 3 KV. The fixed value porcelain RF capacitors across it are also good for 3 KV. Equally important, the tapped inductor is made using 1/4" OD soft copper tubing. Since my tapped inductor is 14T, with a tap at 3T, my radiator appears closer to 1000 ohms. I expect the voltage then is closer to 1000 Vrms (1414 Vpk). In any event, I've had zero issues for several years.

The L|C combination makes this resonant on only 20m. K6MHE wrote an article on how to use a 33' radiator on 20 & 40m: http://k6mhe.com/files/DualBandVert.pdf

I use four quarter wavelength radials. Any unbalanced radiator needs that, to prevent common mode problems. For a vertical, it works well.

But the ordinance doesn't specifically say "no"...sounds like a way of effectively banning towers without being noncompliant to federal law. Here in "The Democratic People's Republic Of Sharon WI" there are no bans on towers, just a max height restriction of 35 feet...[although there are houses higher than that with tripods nd TV antennas on the roof]...but the building permit process is another story here where it's illegal to change a fuse, breaker, switch or outlet in your own house without a permit.
And to think I bought here because no HOA...

Now that's a different thought.

What if someone was to put a tower on the roof. like one of those 4
legged versions. kind of looks like an old windmill tower. No Go?

20216. Re: Feeding a Half-Wave End Fed Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-23 03:52:23 UTC
From: AB2ZY
Topic: 20190 Message: 20216

I had thought the impedance would be higher than that, at least for an end fed horizontal wire. Maybe your radial system brings the impedance down? I was specifically thinking of an end fed wire with nothing but a ground rod for earth.

Out of curiosity, what benefit does your antenna have over a vertical dipole? Additional gain? Aren't there some "unwanted" lobes in the radiation pattern from the length?

I'm not trying to be a dick, just genuinely curious.

The end fed dipole antenna must be matched and can me matched to any feedline impedance without
much trouble and it need NO ground or counterpoise to work well. The matching usually reduces it to
a single band, but it also suppresses harmonics somewhat. It can be mounted vertically or horizontally.

A 1/4 wl vertical is a 37 Ohm antenna that requires a good counterpoise for good efficiency.

From: jo barden
Topic: 20190 Message: 20221

Here's my take on it.

Vertical generally has lower take off angle for us mere mortals with lowish dipoles. Can be made radial free easily without reducing efficiency and it is fun to play!

20222. I needed an 11 meter antenna so I made a dipole. Polarity question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-23 16:18:08 UTC
From: ve5mjb
Topic: 20222 Message: 20222

Hi all, as part of ARES here I wanted to cover off the 11 meter band as well. I took a trucker 4' dual whip and made a dipole. I have read that if I mount this horizontally I will have trouble with local area traffic due to polarization as the majority of people run antennas horizontially. This is a radio that will not see too much action so I do not want to erect another high visable antenna. (Keeps the neighbourhood happy)I wanted to mount this in the attic.

Does any one have any knowledge here, and if so can I acomplish an attic mount system in a different mannor?
Thanks Mark

Have one a friend built for me running East and West. It works as well as my 80/40 ARRL Trap Dipole running North and South. I switch between them for the best received signal.

20228. Re: Tower Ordinance

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-23 19:31:56 UTC
From: Bryan
Topic: 20196 Message: 20228

Hi Joe,

Here are some things to consider. I'm in process to erect a 72' free-standing crank-up (US Tower TX-472) in unincorporated Snohomish County, WA. My lot is 100'x124' and the plan is to erect it 50' from three property lines, just behind my house. With really not all that much trouble, the permit has been OK'd and is ready to pick up.

The very first thing I did (before purchasing one stick of material or beginning the permit process) was to read 'Up The Tower' by Steve Morris K7LXC (www.championradio.com). Steve is a mostly retired tower worker. His book answered all the questions I had and some I didn't know I had. The best advice I can give is to read Steve's book before doing anything else. The picture will be much clearer afterward.

Some will poo-poo working with 'The Nanny State' and effuse that it's better to just do it and hope they won't come after you. Again, read Steve's book before you do anything. If you decide to defy local authority, you'll at least know what to expect in the way of fines, etc.

I never considered a roof-mounted tower but I believe I understand correctly that (in my locale) a roof-mounted structure has no permit requirement and no height limitation. I also believe that a permitted and engineered structure relieves me of most liability in the event of catastrophic failure. My homeowners insurance will cover me as long as the tower meets legal and engineered requirements.

I also wouldn't buy one of those roof towers (made by Glen Martin Engineering and probably others). They're VERY expensive vs what you get. In the past, a mast proved to be a more economical choice for me. A 26' tall rotating mast for my 3-el 15m yagi wasn't all that difficult to design, build and erect.

I must interject something here...with proper rated components, there is no need to reduce power.

If the original statement made below was correct, then none of the AM broadcasters using 1/2wl antennas would be operating..one of them, WLW in Cinci, is 50KW carrier into a 1/2wl Blaw-Knox tower....~14,400 volts of RF at the base of the tower iirc..just imagine what is was when they ran 500,000watts in the 1930s!!

A 1/2wl antenna has about 1.2db over a dipole..(remember the earth would be the other half of this full wavelength dipole..just a 1/2wl dipole is the full length of a 1/4wl vertical)..Lower radiation take off angle (until you get to 5/8wl on simple non colinear verticals)...and not really requiring a stable ground system to make radiation efficiency high as a 1/4wl or 5/8wl would require.

I had thought the impedance would be higher than that, at least for an end fed horizontal wire. Maybe your radial system brings the impedance down? I was specifically thinking of an end fed wire with nothing but a ground rod for earth.

Out of curiosity, what benefit does your antenna have over a vertical dipole? Additional gain? Aren't there some "unwanted" lobes in the radiation pattern from the length?

I'm not trying to be a dick, just genuinely curious.

Topic: 20222 Message: 20230

If you're planning to put it in your attic, fine. If eight feet is too tall for under your roof, put one pole in the closet and make a ground plane with three or four nine foot radials. Vertical polarization is a must... that's what everybody else will be using and you loose sooo much being cross polarized with local communications.

If you live in one of the enlightened rust belt nanny states like NY,
safety is guaranteed by preventing Walmart from selling slingshots.

I ended up buying an EZ-Hang as an impulse purchase at Dayton a few years
ago. A lot of money for a tool I'll only use a few times in my life. It does
work, though.

From: Bryan
Topic: 20190 Message: 20232

As I understand it, the feedpoint impedance is governed more by the proximity of earth below it than anything else. And, ANY unbalanced feedpoint requires a ground. The lower the feedpoing impedance, the lower the ground resistance needs to be. So, for a half wavelength (Hi-Z) end-fed, the ground resistance doesn't need to be all that low.

The reason for the end-fed half wavelength vertical is purely mechanical integrity/complexity. A vertical dipole, if made from tubing, must have an insulator in the middle that can handle the bending moment caused by tilting the antenna up/down. If made using wire, the antenna requires some form of support from above, such as a support rope between the tops of two trees. In both cases, you need to find a way to bring the feedline away from the feedpoint. End-feeding the antenna resolves all of the above. Some day, I may change the feed system to make it work on 40m as well (per K6MHE's article).

In theory, a half wavelength monopole with ground plane exhibits about 2.4 dB gain over a quarter wavelength monopole. The main lobe is closer to the horizon. 5/8 wavelength gives 3dB gain.

20233. Metal Roof Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-23 23:07:28 UTC
From: rrath
Topic: 20233 Message: 20233

Hello to the group. What antenna would be
best to mount on a 100' long, pitched, metal
roof?

Our City Public Works Department is having a
new building built and it will have a metal roof.
The roof is a pitched roof not a flat roof. It will
also house our EOC as a secondary location
(backup location). I am thinking of a vertical in
the middle of the roof. Or should we use a
NVIS antenna or a flat mounted end fed wire
antenna? They really do not want a wire
antenna due to cosmetics. But if I use a small
wire, you would have a hard time being able
to see it. The wire would be pointing West.
The State EOC is West and slightly North.

We only need to talk about 100 miles as a
crow flies, to the State EOC; anything beyond
that is a bonus.

Your thoughts and comments needed.

Thank you.
Rod kc7vqr

The impedance of any element is effected by the impedance of whatever and what all is around it
including it's own energy being reflected back to it, and it's phase. The farther any antenna is
from everything the closer it is to it's theoretical design. (height is very good)

Not quite correct, any dipole no matter how fed is a complete antenna, anything less needs a
counterpoise of some kind to compete it. A quarter wl long wire or rod is not an antenna by itself.

I'm not up on that theory, but I suspect a counterpoise under a wavelength vertical will change
the pattern more than the "gain."

After I sent the post I was thinking about that info as well.

We use 3.985 +/- as primary and 7.245 +/- as secondary. The radio out put is 100 watts.

Certainly one designed for the frequency that you intend operating on.
(and as high as possible)

I'm a newbie but given that 5W radios seem to reach half way around the world with a buddipole I would think you an just clip on to some barbed wire and it'll blast 100W right past your 100 mile target. In other words I don't think the metal roof matters much. I look forward to reading replies from people who actually know this stuff. What kind of antenna does the EOC have you're trying to reach? I took a look at Comet (arbitrary) and saw this one:

(CHA-250B) http://www.cometantenna.com/newPro_detail.php?ID=234

A vertical for use from 3.5 to 57 Mhz.

20241. Very long Open Wire Line ?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-24 01:29:22 UTC
From: Dave
Topic: 20241 Message: 20241

More years ago than I care to admit I read an article in one of the ham rags of the day (73?) about using open wire line as a feed method for a very long run. I vaguely recall they used some sort toroid transformer at the ends to move back to 50 ohms.

So here is the good news: I live on 10 acres (300' wide 1500' long ..eat your heart out) bad news is the area where I'd like to put the antenna farm is about 500' from the shack. For the purpose of this exercise we are considering 160-10M operation,. I could run LMR600 at 500 ft the loss would only be 1.5 db at 28MHZ but the cost would be on the order of $1000. I have LOTS of #12 laying around so I was thinking of maybe running an open wire line out there and use transformers at either end to convert to 50 OHms. The feed line will run about 10' off the ground (avoids getting taken down by the deer)

Questions
1) Would an open wire system like this be more subject to noise and even radiate itself?

2) What would the losses be on a 500' run using #12 at 28 MHz

3) What is the best I can hope for in the way of losses in the 50 ohm matching transformers

4) Anyone there actually done this? War stories?

If kept balanced no. It is frequently good to twist it mildly.

> 2) What would the losses be on a 500' run using #12 at 28 MHz

Less than anything else, and the higher the impedance the less the losses. The insulating pegs
must tolerate the weather, that's easier to say than to do.

> 3) What is the best I can hope for in the way of losses in the 50 ohm matching transformers

Negligible and they are called baluns, specifically 1:4, 1:6: 1:8, but the losses at 450 Ohms and
higher characteristic impedances the two baluns are not really necessary in most cases.

> 4) Anyone there actually done this? War stories?

Done every day by thousands of hams and commercial installations, it is the normal way to feed
Sterba arrays and many other huge antennas. (as in in mw & HF broadcasting)

I end fed a 10 wavelength long 10 meter long wire with feedline made with no.12 single strand insulated wire using oak 6 inch 3/4 inch squared strips boiled in paraffin for a while to waterproof them and a tuner in the shack. I just drove a 1/4 by 1 inch long staple into each end of the sticks to hold the wires, worked good! The wax is a must and wood strips must be very dry when put in the wax.

From: AB2ZY
Topic: 20190 Message: 20246

You gave me an epiphany!

Since efficiency is determined by the ratio of radiation resistance to Rr plus losses, you gain quite a bit of efficiency compared to feeding a radiator at a low impedance point. I knew about the mechanical limitation, but was stuck in a low impedance minset.

Thanks!

Al

I did say "modestly rated components". Broadcasters do not need frequency agility, which I would assume simplifies the variable components needed for the matching network. WLW doesn't move from 700 kHz!

Topic: 20233 Message: 20251

I have a pitched steel roof and 3 resonant dipoles on a 33 ft push up pole so the centre of the dipoles are about 22 ft higher than the lower edge of the roof my lot is long and narrow so the wires are more or less parallel with the length of the building and spaced about 1.5 ft from the eave . using a standard wall mount pole bracket . I have not noticed any major problems caused by the close proximity of the steel roof . it is grounded by the cast iron 4 " stack , that is probably not a very good ground .

Larry, what is the length of your end fed antenna and do you use an unun? Signals on my 63 ft end fed are lower on 80 and 40 meters than my trap dipole but about the same on 20-10. It also allows me to operate on 12 and 17 meters. Greg, K4PVA.

It is really a Windom. Off center fed dipole fed with coax to a 4:1 balun
at the top.

20256. Re: [ham-antennas] Very long Open Wire Line ?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-24 05:13:17 UTC
From: roger.h@comcast.net
Topic: 20241 Message: 20256

I presently have a 80/75 meter loop at 227' from the shack. 150' of 450 ohm ladder line to 4:1 balun then LMR400 the rest of the way. Also a 145' ZEP feed with 300 ohm ladder line down to LMR 400. I'm getting the materials together to make my own ladder line. will be 600 oh m. I am also presently laying 2 150' runs of Cable TV 1/2" hardline. Plus another run of RG6/quad and burying the lmr400 with all this. Now I have to put homemade copper pipe connecters on the ends of the hardline.

You know. I might be a lot better to use the free giveaway hard line from the cable people. It's pretty low loss. I got it free and you can have if you come to TN. The connecters are simple to make. All this stuff is wearing me out. 73, Roger, W4IV

I end fed a 10 wavelength long 10 meter long wire with feedline made
with no.12 single strand insulated wire using oak 6 inch 3/4 inch
squared strips boiled in paraffin for a while to waterproof them and a
tuner in the shack. I just drove a 1/4 by 1 inch long staple into each
end of the sticks to hold the wires, worked good! The wax is a must and
wood strips must be very dry when put in the wax.

I have gad a set of these traps for quite a while and cannot find anything
even on Google for these. I thought they were for an 80/40 antenna but they
don't behave that way.

And an easy way to dry the wood, is to now don't laugh, place them in
the microwave over set on a low setting. And boil out all the moisture.

be careful tho, i have still have had them char somehow, so i guess
they still could catch on fire. why or how i do not know because i was
always led to believe it is the water molecules being agitated by the
radiation that makes the heat. and once all the water is gone then
what happens?

Given you want to cover a fairly small radius (1-200 miles) I would consider an antenna designed for NVIS communications . That is what the military uses for battlefield comms. There are lots designed for that purpose but the only one that comes to mind right now is the Hi Q - I have NOT used one of their antennas and I am NOT suggesting you buy that antenna , only pointing you in a direction that I believe will help. NVIS antenna cover a good 3-400 mile radius very effectively cause the signal is emitted " Near Vertical "

Hope this helps

I work South Africa and Oceania consistently from Western Canada running 50-100 watts on 40 at night. The SATERN digital net 7065 KHz usually covers coast to coast at 0100Z. And thats with only a dipole in the big pine tree.

Antennas and bands are funny, I'm working quite a bit on 10 through my 40 meter dipole.

Joe: Actually any number of organic compounds can be excited by microwaves , not just water.... The out-gassing of moisture from wood is a very slow process since wood is relatively impermeable to begin with. Well actually as I think about it wood is "designed" to pass moisture in the z-axis (sap flowing in the tree) but not at all in the X & Y axis ..takes a relatively LONG time to thoroughly dry wood.
A safer way is to dry the wood spacers in the xyl's oven over night at around 160-180 F. The next night you can submerge them in a tray (go to Goodwill dont use the XYL's good baking stuff) with the paraffin over night at the same temperature.

ALL: The article I vaguely recall in the original post used a 4 wire system instead of two ...besides possible reduction in I/R losses what are the other advantages of this approach? Open wire seems pretty low loss to begin with

Brian: I looked (and registered) at www.cebik.com.. But found the site a little dysfunctional to navigate (kind of like running a maze) and nothing useful on the design, care, feeding and maintenance of really long (500+) feed line systems popped up in the search engine , mostly routine stuff about feeding dipoles with relatively short (100') feeders.

A well balanced ladderline does not radiate and does not pick up more noise as a coax .... (my findings are that sometimes it is the other way around!!)

Losses??? In balanced line??? On a 160m run??? On 10m?? ... answer NOT NOTICEABLE .... lower as the best coax you can buy!!!

No matching transformer on both sides!!
On antenna side connect direct (I would recommend a big loop)

On shack end: a balanced tuner ... coax in/ balanced out
Best is a balanced tuner with balun at the input side ...
But you can also use an unbalanced tuner with balun at the output side (but with a bit higher losses!)

20267. Halfwave end fed antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-24 17:18:07 UTC
From: xzs5ham
Topic: 20267 Message: 20267

Hi & first post to the group - I've been following the halfwave feeding saga & think some members might be interested in a design that was very popular in South Africa (& maybe still is)- google for "ZS6U minishack special" & you can find reprints of the construction article from Radio ZS magazine with all the theory regarding matching & antenna lengths. This is a pre WARC band design using a simple L match & needs no radials except on the lowest operating band on which it's a 1/4 wave & requires 1 or 2 radials. Worked loads of dx using it - in the article its shown as an inverted vee but works fine as a straight wire sloper too & used to run it in stealth mode from a 4th floor apartment window to a tree below. The tuner withstood 400w from my old G2DAF linear so what the RF KV was at the feedpoint is anyones guess? - RF in the shack using QRO is the only problem but but can be got around.
WARC bands too?-possible with the correct ATU coil taps plus a few radials might be required as the feedpoint will be lower impedance on these bands.
Jerry G4GGZ ex ZS5YH

I agree with Sig,

The nature of open line is it is self shielding, (as long as it is balanced) if there is an unbalance in the system then you open it to many questionable happenings.

But think until recently all TV was 300 ohm open line. It still has less loss than any coax out there. You just need to make sure you know how to use it correctly.

I remember a neighbor put up a 60 foot tower to get better TV. And complained that he had a better picture with his rabbit ears on top of the TV. When i came over it was easily seen what he did wrong. He did use 300 ohm twin lead as the antennas were that feed style. and he very neatly every two feet or so neatly taped the twin lead along the leg of the tower. it all was a very pretty job. he he he..

Subject: [ham-antennas] Very long Open Wire Line ?

More years ago than I care to admit I read an article in one of the ham rags of the day (73?) about using open wire line as a feed method for a very long run. I vaguely recall they used some sort toroid transformer at the ends to move back to 50 ohms.

So here is the good
news: I live on 10 acres (300' wide 1500' long ..eat your heart out) bad news is the area where I'd like to put the antenna farm is about 500' from the shack. For the purpose of this exercise we are considering 160-10M operation,. I could run LMR600 at 500 ft the loss would only be 1.5 db at 28MHZ but the cost would be on the order of $1000. I have LOTS of #12 laying around so I was thinking of maybe running an open wire line out there and use transformers at either end to convert to 50 OHms. The feed line will run about 10' off the ground (avoids getting taken down by the deer)

Questions
1) Would an open wire system like this be more subject to noise and even radiate itself?

2) What would the losses be on a 500' run using #12 at 28 MHz

3) What is the best I can hope for in the way of losses in the 50 ohm matching transformers

4) Anyone there actually done this? War
stories?

20270. wire loop antenna.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-24 22:06:33 UTC
From: jeffrey l
Topic: 20270 Message: 20270

I currently use a doublet 130 ft long 21 ft up, and fed with open line , This is fine for local , out to 1200 miles but noise levels can be a major issue.

I am thinking of a loop antenna and due to the size of the backyard 45' x 36' , i think i should be able to get a 7Mhz full wave loop up to about 21'-24' above ground.

I currently use an MFJ 491D tuner, and I have 3 HF sets, ICOM 718&AUTO TUNE(belongs to No1 son), KENWOOD TS520S, and A YEASU FT77, these are set up so that I can switch them into the antenna circuit as I wish.

Will the 7Mhz loop tune down to 3.5Mhz and up to 10Mhz ???

Jeff,
We have a 40 meter loop at about 25 ft and it had no problem tuning to the higher frequencies up to ten meters but we did not give a try to tune down to 80. We used a ts570d and the AT of the radio was sufficient enough.

73,

jojo

IMHO, a 40M loop will work great on some higher bands. Below is a chart of my 80M size loop. You can see that all the HF bands come within a reasonable point of resonance. Looking at a 40M size it shows 10,15 and 20 are even numbers. 12&17M come in as .5 and wont tune as well. I run a 80 size loop , tweaked to 20M and get great gain on the upper bands. A 40M loop is not easy to tune to 80M

Topic: 20270 Message: 20278

Opps, it looks like junk. I copied a Excel spread sheet of mine and did a copy & paste. Can you read Excel , I can send you the original direct. The basic information is
1X loop is a 100 Ohm antenna , a 2X loop and larger close to 200 Ohm

2X in length loop, or greater can be matched with 50 Ohm coax and a 4:1 Balun if
the overall length of the loop is a multiple of the length at that frequency

Even Multipliers will make it a resonate antenna, A 4X and 8X loop will match
the most bands when used with a 4:1 Balun

With the correct resonate length of the antenna no tuner adjustment is needed
on the 7 bands.

Hello Jeff

Loading a 40 meter loop on 80 causes ineffe icency. The only way I would do it would be to take the coax connector off and short the ground to hot and load. Or just load inner conducter of coax and let other side be open and feed as a long wire.

Subject: [ham-antennas] wire loop antenna.

I currently use a doublet 130 ft long 21 ft up, and fed with open line , This is fine for local , out to 1200 miles but noise levels can be a major issue.

I am thinking of a loop antenna and due to the size of the backyard 45' x 36' , i think i should be able to get a 7Mhz full wave loop up to about 21'-24' above ground.

I currently use an MFJ 491D tuner, and I have 3 HF sets, ICOM 718&AUTO TUNE(belongs to No1 son), KENWOOD TS520S, and A YEASU FT77, these are set up so that I can switch them into the antenna circuit as I wish.

Will the 7Mhz loop tune down to 3.5Mhz and up to 10Mhz ???

From: Larry Tooley
Topic: 20241 Message: 20280

The trick to keep open wire line noise free is to twist it about once a foot. The noises then cancel out. The old 300 ohm TV twin leads were always twisted if installed right. The 2nd advantage is the line doesn't sail in the wind as bad.

> 1) Would an open wire system like this be more subject to noise and even radiate itself?

If kept balanced no. It is frequently good to twist it mildly.

> 2) What would the losses be on a 500' run using #12 at 28 MHz

Less than anything else, and the higher the impedance the less the losses. The insulating pegs
must tolerate the weather, that's easier to say than to do.

> 3) What is the best I can hope for in the way of losses in the 50 ohm matching transformers

Negligible and they are called baluns, specifically 1:4, 1:6: 1:8, but the losses at 450 Ohms and
higher characteristic impedances the two baluns are not really necessary in most cases.

> 4) Anyone there actually done this? War stories?

Done every day by thousands of hams and commercial installations, it is the normal way to feed
Sterba arrays and many other huge antennas. (as in in mw & HF broadcasting)

I'm a newbie but given that 5W radios seem to reach half way around the world with a buddipole I would think you an just clip on to some barbed wire and it'll blast 100W right past your 100 mile target. In other words I don't think the metal roof matters much. I look forward to reading replies from people who actually know this stuff. What kind of antenna does the EOC have you're trying to reach? I took a look at Comet (arbitrary) and saw this one:

(CHA-250B) http://www.cometantenna.com/newPro_detail.php?ID=234

A vertical for use from 3.5 to 57 Mhz.

I agree with Sig,

The nature of open line is it is self shielding, (as long as it is balanced) if there is an unbalance in the system then you open it to many questionable happenings.

But think until recently all TV was 300 ohm open line. It still has less loss than any coax out there. You just need to make sure you know how to use it correctly.

I remember a neighbor put up a 60 foot tower to get better TV. And complained that he had a better picture with his rabbit ears on top of the TV. When i came over it was easily seen what he did wrong. He did use 300 ohm twin lead as the antennas were that feed style. and he very neatly every two feet or so neatly taped the twin lead along the leg of the tower. it all was a very pretty job. he he he..

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-25 11:43:42 UTC
From: Frank Kirschner
Topic: 20233 Message: 20283

It seems to me that a metal roof would provide an optimum location for a screwdriver-type antenna like the TarHeel or something similar. I used a KJ7U antenna with a few radials on the ground, and it did very well. I worked 24 states in about an hour on 160, and made many contacts across the HF band. On 160, I swapped the 72" whip for a ten-foot collapsible whip from MFJ for greater efficiency and easier tuning.

Up on the roof, with all that metal as a ground, I would think a short vertical would do very well.

Subject: [ham-antennas] Very long Open Wire Line ?

More years ago than I care to admit I read an article in one of the ham rags of the day (73?) about using open wire line as a feed method for a very long run. I vaguely recall they used some sort toroid transformer at the ends to move back to 50 ohms.

So here is the good news: I live on 10 acres (300' wide 1500' long ..eat your heart out) bad news is the area where I'd like to put the antenna farm is about 500' from the shack. For the purpose of this exercise we are considering 160-10M operation,. I could run LMR600 at 500 ft the loss would only be 1.5 db at 28MHZ but the cost would be on the order of $1000. I have LOTS of #12 laying around so I was thinking of maybe running an open wire line out there and use transformers at either end to convert to 50 OHms. The feed line will run about 10' off the ground (avoids getting taken down by the deer)

Questions
1) Would an open wire system like this be more subject to noise and even radiate itself?

2) What would the losses be on a 500' run using #12 at 28 MHz

3) What is the best I can hope for in the way of losses in the 50 ohm matching transformers

4) Anyone there actually done this? War
stories?

73

You could change the pattern by moving the legs, is there a reason you have not tried this?

No, I was meaning the Maximum Permissible Exposure to the people in and
around the Metal Roof... You load that thing up with 1 kilowatts or so
and you are effecting your body to high levels of RF. I'm just thinking
of the safety side of things, not saying it can't be done.

20290. HF Delta Loop

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-25 14:19:59 UTC
From: dj_philonline
Topic: 20290 Message: 20290

Hi, I recently made a quick HF vertical delta loop and decided to share my findings, the antenna started life as a single prowhip 6M roach pole HF vertical with a 9:1 unun which worked great at my former qth high up in the Northumberland hills but down here in the deep valley with trees everywhere was not very good at all with the signals being very low and the noise from the lattice of pole fed overhead domestic AC, I am also under a vast umbrella of overhead telephone cables with three heavily loaded poles within yards of my property, we are in a very built up area with small gardens and elderly neigbours with no understanding or tolleration of radio so I found out when the 30 something foot large metal vertical HF I errected in the same possition as the delta caused great concern to them, not to worry it was just as noisy as the prowhip so it was removed and now resides in a field in Ireland and doing very well so I here.
Next step was to try a wire dipole which I did not realy have the room for and was still noisy in the inverted L shape and as I am only foundation licence class here in the UK did not want to loose any of my 10W via traps, then tried a bamboo constructed 2 band cobweb, the noise problem was a bit better but signals still very low due to height also received poor TX reports compared to other antennas tried.
Loops seemed my only and final option as hieght was not required, reports of reduced noise levels and good performance in areas with poor reception "thats me"
To start with the 9:1 unun in hand needed to be a 4:1 balun easy so it seemed break it open and rewind it! but after I opened it and looked inside I decided a new better quality toroidial and new wire would be more fitting.
I then ordered an identical 6M roach pole (found on ebay very cheap) to create the delta supports and some Racal clansman cable to put up with our very high winds.
Cut the roach pole tubes bit by bit on the tips untill the wire passed through without force which shortend the poles by 10" the set about making the mounting board (U clamps already in the shed after mounting my VHF/UHF beam and rotator 14ft above the chiminy stack just to hear our local repeater)
Drilled and stuck it all together and was amazed to hear stations 30 miles away on 40M in an area very difficult for me to work while it was laying flat in the garden on three chairs for support about a meter off the ground with a noise level of 0, at that moment I decided to weather proof this trial version and get it up a height, the delta by total accident is resonant for the high end of the 10M band and no tuner is required with a 1.2:1 swr which is great at the moment as this band is wide open, all other HF bands I use (160 and 80 not tried) easily tune with the MFJ 945E to 1.1:1 with low noise and good reports, I did believe that a vertical delta loop was directional and I have this one with the open loop facing East/West but I still get good signals and reports from the South? can somebody explain this please?
I am now getting much better use of my little FT-817ND now I have built and erected a delta loop and even spent a few hours SWL with great pleasure, anybody in a similar situation as myself give it a go, it is well worth it.
Photo album added(Phils Delta Loop) with construction pictures and final mounted possition pictures.

Gentlemen ,
A vertical would be a great antenna for DX - but as I read it , he isn't wanting DX. He just wanted to use it for ECOM to the main station about 100 miles away .... with a vertical you could probably " launch " right over their heads. NVIS antenna will put it straight up and back down in a tighter radius

Because I think he is asking about vertical vs horizontal polarity, not signal pattern.

Hope this do not sound silly but why not just use a dipole cut for 11 meters.
You could change the pattern by moving the legs, is there a reason you have not tried this?

ke7sbe

>Hi all, as part of ARES here I wanted to cover off the 11 meter band as well. I took a trucker 4' dual whip and made a dipole. I have read that if I mount this horizontally I will have trouble with local area traffic due to polarization as the majority of people run antennas horizontially. This is a radio that will not see too much action so I do not want to erect another high visable antenna. (Keeps the neighbourhood happy)I wanted to mount this in the attic.

I doubt you will see much difference on 10 or 11 meters... when the band is open, like now, verticals talk to horizontals all the time, no problem, I think that would be more of a problem on VHF than ten meters. Certainly not any more than having to mount the antenna in your attic.

Disagree

LOCAL signals (25 miles or less) from VERTICAL (mobile) antennas will be reduced by as much as 20Db.when using a HORIZONTAL antenna to communicate from the the "Base Station" ..been there done that on 10M & 6M transmitter hunts. When we were the fox we used to switch the polarization of our antenna every 10 minutes or so to throw off the hounds

DISTANT SIGNALS (100+ miles) will not be affected much if any because of the dispersion affects of SKIP propagation. Long distance communication then becomes more a function of the signal arrival and take off angle more than polarization

20296. AW: AW: [ham-antennas] Very long Open Wire Line ?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-25 17:45:27 UTC
From: Siegfried Jackstien
Topic: 20241 Message: 20296

I have "only" 40m to my loop ... but a friend from me feeds his doublet over
120m of ladderline ... so length is not ac problem with ladderline :-)
...
My loop is not symmetrical 100% ... so i have a slight imbalance at the
feeding line ... a light twisting of the line helped to reduce noise-pickup
....
But the noise level was low anyway ...
I can just barely notice if my sat receiver and tv is switched on (a slight
noise when preamp is on on some bands but VERY low)

Without turning the line the noise was "a bit" higher ... but also very low

I had a dipole here (same feed system) that picked up more noise and lower
signals ... so s/n ratio is better now with my 168m loop

I can not say how high (or low) the noise would be with coax ... cause I
always use ladderline for this antenna

Why not simply try it and see for yourself how it *actually*, really
truly works when on the air??? !
Easy enough to do.

Playing around with any antenna sure is fun, isn't it?
They give great bang for the buck too, usually.

AGREED ... BUT I FEED MY LOOP WITH A RESONANT LENGHT OF LADDERLINE
I can use the topband loop on nearly all bands without tuner :-) (just a
balun at the shack end)
But I change the feedingline length for some bands

>
> So here is the good news: I live on 10 acres (300' wide 1500' long ..eat your heart out) bad news is the area where I'd like to put the antenna farm is about 500' from the shack. For the purpose of this exercise we are considering 160-10M operation,. I could run LMR600 at 500 ft the loss would only be 1.5 db at 28MHZ but the cost would be on the order of $1000. I have LOTS of #12 laying around so I was thinking of maybe running an open wire line out there and use transformers at either end to convert to 50 OHms. The feed line will run about 10' off the ground (avoids getting taken down by the deer)

I have not personally done it, but: Ranch houses out here in the West were built in the canyons and valleys because that was where the water was. When television came the ranchers put up long yagi antennas on the highest butte/hill above the ranch house and ran 300/450 ohm open line to the house. Sometimes up to a mile. They got good reception unless the transmitter antenna was really too far away.

So, the length of the open line you will be running will not be a problem at the lower frequencies.

Paul, KD7HB Central Oregon

Feed the loop away from the houde (with ladderline) ... now the opposide
end (opposide of feeding) is close to house .... place that close to a
window frame (if needed ad a short eun of ladderline to the frame
Now you can rasy open or close your 40 m loop

What do you have when open? ... a bent 80m dipole !!! :-)
So Easy to tune on the 80m band when the bridge is open
But pay attention! There is HIGH voltage at that point ...
...
By the way ... if you have room for a 130m doublet ... why not make a BIGGER
loop ... use all space available ... and even if you have to zig-zag it a
bit ... every meter of copper in the air counts!

Greetz
Dg9bfc
Ps I have a ladderline fed loop here for topband (168m) ... but use it on
ALL bands with GREAT RESULTS!

From: Richard Schmuke
Topic: 20233 Message: 20303

I would make sure the bottom of the J-Pole antenna was at least 1/4wl above the roof.

For HF bands I had a 40M vertical in the middle of my work shop with a 55x70 foot roof but because the steel panels are not electrically bonded to each other I had to add radials to the vertical.

Rich ,KDØZZ , ☺

from the middle of Missouri , out in the sticks with the hicks and the ticks.

Subject: Re: [ham-antennas] Re: Metal Roof Question

I have a 2 meter j-pole I am thinking of mounting right in the center of
the meta roof on my house! any thoughts on this? Ed

20305. paladin PA-1700 desoldering tool question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-26 02:21:26 UTC
From: pchapman920
Topic: 20305 Message: 20305

Anyone have advice on how to replace the foam insert on this tool or a manual that may include the instruction. Found it after it had sat in a box for over ten years and the foam has rotted. Really sucks as now it does not suck but is in great shape otherwise, and would cost $25 to replace the whole tool. Trying to reclaim a couple of silver plate reducers I let solder get in the threads and also add a band element to an existing dipole at the balun pigtail where a cleanup would be beneficial.

From: pchapman920
Topic: 20190 Message: 20306

If you have free or cheap long distance phone, I would go that route, it may bear more weight with them. Otherwise I did see a manual for $2.95 on ebay. Just might add that I have called MFJ twice for support over the last few years, and both times, they treated me well. It was minor stuff, but all was OK in the end, and the last call they said no problem returning under warranty. I think everyone knows there is a long history of QC issues there, but although a short record for me, do not have a complaint with phone support.

try putting the reducers on the end of a 40 watt iron with a conical tip and let it heat up good then use a paper towl or a dry rag (don't use a damp one , the steam burns, been there done that) to clean the threads or if you have any of the small gauge solder wick it may work .

Nice size piece of land,,, but why don't you do a loop plus a couple of full wave dipoles? We are on 7.5 acres here and I am working on building a double full wave loop that will be about 15 feet off the ground, and then 3 fullwave dipoles for 160, 80, 40 meters. Just a thought for you to has over.

For the purpose of this exercise we are considering 160-10M operation,. I could run LMR600 at 500 ft the loss would only be 1.5 db at 28MHZ but the cost would be on the order of $1000. I have LOTS of #12 laying around so I was thinking of maybe running an open wire line out there and use transformers at either end to convert to 50 OHms. The feed line will run about 10' off the ground (avoids getting taken down by the deer)

The stand of "organic antenna masts" (80' trees) is 400' (600' to the center) away ...nothing really suitable closer ....once out to the wood lot I plan eventually on putting up trapped 80/160 inverted L's in Phased array.. plus lots of other wire for the other bands ..room out there to put a 3 element wire beam pointed at Europe for 40 & 30 plus a lot of other "fun" wire projects, possibly two half squares in phase for 40 and so on

Hello Jeff. Try this full wave delta loop on page 4-4 and 4-5 on ARRL (More wire antenna cliassics volume 2). You will be pleasently surprised I was sceptical at first but when I had it up finanally it played really good. It's in the triangle shape with the apex at 50' up my tower with 2 legs shooting out and down to 2 corner posts atached at 6' from ground. Of course the back 93' stretched tight at 6' level all away across. I then ran 157' of 450 ohm ladder line to 4:1 homemade balun. Then lmr 400 to remote coax switch them too shack which was 127'. I to like the low loss. The distances are a swag but close.of coax. It's cross polarised but with low and high angle radiation. This aloows you to work close in and DX. I have over a hundred countries since Feb just playing around. Boy is it quiet. The articile is by Doug Demaw. Try it you'll like it. I put mine at 3.650. The SWR is useable on several bands. I am going to put 2nd one in different direction. W4IV, 73, Roger PS: I feed at the corner post at 6' level.

I am going to feed with open wire , do not like coax due to loss it incurs,

I still have to make & mount the extra 2 supports, required.

Hi Rod,

I use to live in a row home with a flat metal roof. I had a Butternut HF9V on the top metal roof with radials. 33 feet up from the ground.

I took the ground of the antenna to the roof and to a #4 AWG solid copper wire to a ground rod.

The setup worked very well. I could break pile ups on DX with 5 watts. I later had to replace the metal roof with a rolled roof. I kept the same basic setup. Worked just as well but I would have liked to keep the metal roof.

Good luck. Be careful up on the roof.

Topic: 20290 Message: 20318

Phil,

Good to read that your experience with loops has got you the results that you are wanting. The thing about loops they are polarized depending on the place of the balun. If it is at the top it is horizontal and if it is at the bottom it is vertical polarized.

Most antennas will TX in ways that it is not suppose to that is the way wire antennas work.

If you are looking to get both polarization then you may try to put the balun 1/4 of the way up on one of the legs. /_\. I tried this at one of our QSO party and I work a VE station from central K4 land, where I was running a TS430 at 60w. in a valley. The I worked a K6 from the same location. I was working stations as close as Alabama USA.

As for the receive the loop is a wonderful listener it get the signals no matter what polarization the are.

Harold/KD8DVY

--- In ham-antennas@yahoogroups.com, "dj_philonline" <dj_philonline@...> wrote:
>
> Hi, I recently made a quick HF vertical delta loop and decided to share my findings, the antenna started life as a single prowhip 6M roach pole HF vertical with a 9:1 unun which worked great at my former qth high up in the Northumberland hills but down here in the deep valley with trees everywhere was not very good at all with the signals being very low and the noise from the lattice of pole fed overhead domestic AC, I am also under a vast umbrella of overhead telephone cables with three heavily loaded poles within yards of my property, we are in a very built up area with small gardens and elderly neigbours with no understanding or tolleration of radio so I found out when the 30 something foot large metal vertical HF I errected in the same possition as the delta caused great concern to them, not to worry it was just as noisy as the prowhip so it was removed and now resides in a field in Ireland and doing very well so I here.
> Next step was to try a wire dipole which I did not realy have the room for and was still noisy in the inverted L shape and as I am only foundation licence class here in the UK did not want to loose any of my 10W via traps, then tried a bamboo constructed 2 band cobweb, the noise problem was a bit better but signals still very low due to height also received poor TX reports compared to other antennas tried.
> Loops seemed my only and final option as hieght was not required, reports of reduced noise levels and good performance in areas with poor reception "thats me"
> To start with the 9:1 unun in hand needed to be a 4:1 balun easy so it seemed break it open and rewind it! but after I opened it and looked inside I decided a new better quality toroidial and new wire would be more fitting.
> I then ordered an identical 6M roach pole (found on ebay very cheap) to create the delta supports and some Racal clansman cable to put up with our very high winds.
> Cut the roach pole tubes bit by bit on the tips untill the wire passed through without force which shortend the poles by 10" the set about making the mounting board (U clamps already in the shed after mounting my VHF/UHF beam and rotator 14ft above the chiminy stack

just to hear our local repeater)
> Drilled and stuck it all together and was amazed to hear stations 30 miles away on 40M in an area very difficult for me to work while it was laying flat in the garden on three chairs for support about a meter off the ground with a noise level of 0, at that moment I decided to weather proof this trial version and get it up a height, the delta by total accident is resonant for the high end of the 10M band and no tuner is required with a 1.2:1 swr which is great at the moment as this band is wide open, all other HF bands I use (160 and 80 not tried) easily tune with the MFJ 945E to 1.1:1 with low noise and good reports, I did believe that a vertical delta loop was directional and I have this one with the open loop facing East/West but I still get good signals and reports from the South? can somebody explain this please?
> I am now getting much better use of my little FT-817ND now I have built and erected a delta loop and even spent a few hours SWL with great pleasure, anybody in a similar situation as myself give it a go, it is well worth it.
> Photo album added(Phils Delta Loop) with construction pictures and final mounted possition pictures.

Try adding a few inches to the feed line and then try 10M again

From: James E.
Topic: 20270 Message: 20323

Is that article on the web somewhere or do I need the book? Would sure like to check it out.

I haven't managed to get an HF antenna up yet, as I have certain challenges of terrain and space (as well as money and chronic illness), but I am coming to the conclusion that some sort of wire loop will be the ticket for me. And if I can get one antenna to give me dx and short distance, that would be even more ideal.

73,
James, KF7RHM

Man that is a really complicated circuit isn't

The magic must be in the winding coil ...I'm guessing that is some kind
of ferrite rod from the photo with fancy plastic caps on the ends

20326. Another Loop Antenna Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-27 13:44:36 UTC
From: oceanbiz01
Topic: 20326 Message: 20326

Hello All

I am looking for a practical answer to a practical question.
Simply put, I have built a coax receiving loop for 160 meters RECEIVE only.
It seems to work well compared to my K9AY RX Loop.

http://www.k3zxl.com/Loop.htm

My question is:

Is it necessary to either :
A) Ground the junction box to a ground Rod ? The coax shield is grounded to the box internally
B) Is a ground plane or radial field required under the loop?

I am curious what source of info provides the answer such as a model of the antenna or some simple theory that I can understand.

So far, in my research of people using loops, I see no info on grounding. Some people put loops in their attics, or gardens or operate portable with loops.

Any info will be greatly appreciated.

Dan K3ZXL

No antenna "REQUIRES" a ground, a half of a dipole needs a counter poise to complete it.
Using dirt (and a 8 or 10 foot rod) is a poor substitute for a counterpoise.
If a loop of any kind needs a counterpoise it can't be much of a loop.
I would have connected the feedline to the outer and left the inner conductor alone, did you try that?

Ron
This is a magnetic loop. The outer (shield) is split at the top of the loop. The shield acts as an electrostatic shield. See the schematic of a magnetic loop at the bottom of my web link in my original email. This is standard practice for a mag loop.

Best Regards
Dan Schaaf

Hi Guys,I can understand your frustration, I would be too if I had that
problem.
I have had an account for several years without a problem.
Maybe if you contact Tomas he can do something to correct the problem
Ko4BB is a nice site,but Tomas has many files that Ko4BB does not.'
Dave Cole, I hope you got the file when I sent direct when I posted a reply.
I surf the net for Ham related projects and try to help other when I can.
I have much time for the computer!
I had open heart surgery ,4 bypasses,and pace maker, several months ago ,
and my wife, dislikes me to stay out of site vry long.
73 to all Ken

"Please report anything that doesn't seem to work OK.
Look under Help if you experience any problems."
Best Regards
Tomas Larsson

If anyone wants to contribute or have other great ideas/knowledge for the site itself (not uploading stuff), please Contactme.

Dan

in my opinion and experience the grounding of a magnetic loop is not a
requirement.

Nice construction by the way ...very professional. The results that you
list in actual usage seem to indicate that the thing is working as
described. The next project might be a simple preamp for the beast for
weak signal work but again in my experience the preamp doesn't usually
add all that much and in fact can in some instances slightly degrade the
signal to noise performance which is what loops are all about to begin with

Hi Dave

Thanks for your reply.

In fact I am using a Clifton Labs 20 db preamp in the shack with an A/B switch to switch between the K9AY Loop and the coax loop for test purposes. The preamp can be switched in and out also.
I have BCB filter that I can switch in/out also from Clifton labs but it has about a 1 or 2 S Unit deop in signals and noise when switched in.

20334. multipile 2M/440 cm antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-27 20:53:21 UTC
From: sardean
Topic: 20334 Message: 20334

I was told by a friend that having two VHF/UHF antennas on my roof was counter productive. I had one at the back not connected to the radio and one in the middle of the roof connected to my 857D. Its when I was having my static crashes and I wanted to know if it was my antenna, and I found out it wasn't.

My question is will it hurt to have two antennas on the roof well away from each other when one is not connected to any radio.

Why not switch between them. The more antennas the better.

20336. adding phasing stub to 1/4 wv 2meter (mobile ant.)for 70cm dual band operation

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-27 22:25:58 UTC
From: kb3svj@ymail.com
Topic: 20336 Message: 20336

Hello All:

I seem to recall an article where a fellow wanted to be able to use his existing 2M 1/4 wave mobile antenna for 70cm operations since he had a 2m/70cm dual band TX/Rx mobile rig. Needless to say,
I can't find it in my QST's and CQ mags.

How he did it was to bend a piece of stout wire (what he would call a phasing wire) into a "j" shape. I think the new element was roughly 1/4 wave long (not sure where in the band) with the first bend at only about 1" and the second bend =/< then an inch. The inch portion would hold the new element away from the main 2m element by an 1" while the second bend would provide the mating surface to attach new element to the old. I think he sweated the two together.

Now, the orientation of the new element was upside down, not right side up as one would expect to see in a j-pole. My guess is that the setup is acting like a parasitic element (although I guess a true parasitic element would not have physical contact with the main radiating element-what do I know-advise accordingly plz) and allowing for the radiated signal to be emitted.
While he did claim that the SWR was OK on both bands, his assessment-in a nutshell- was that he was merely able to communicate on 70 cm in addition to 2m. He found no change (I'm assuming no negative change) in is 2m performance with the addition of the stub.

Too, I am wondering it the radiation angle higher for 70cm would be higher then if the antenna was solely 70cm 1/4 wave or if it would have the same angle of takeoff as said mono band 1/4 wave.

Thanks

John kb3svj

ps: I built a simple 1/4 antenna system for one of our club members who's less fortunate then I; the main feature is that he merely has to switch out the radiating element and the radial elements from a barrel connector. Mind you, it's not an all weather antenna but it should afford him the ability to get into repeaters while his apt (restriction on ext. antennas) on either band (one at a time. That's why, I was wanting to make a dual band antenna in the manner described.

So side by side how does your new loop compare to the k9AY loop?

Hi Jim

I use one for my mobile jeep insallatiopn and love it. It works fantastic and I also have another mobile install that does not have a scorpion and I can tell you that this is a fantasitc antenna.

Let me know if you have specific questions.

Long path is rare on 160M , although I have had some memorable QSO's
that way. Comparing signals from Europe is probably good enough ....much
longer than 3000 miles is usually multi hop anyway and the arrival angle
is the same

<<< multi hop anyway and the arrival angle
is the same >>

yes, but there is attenuation with each hop.

I am thinking that perhaps the narrow beamwidth and High Q of the mag loop offsets the gain advantage of the untuned wideband K9AY Loop and the results may be equal in the end.

20342. RE: [ham-antennas] multipile 2M/440 cm antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-28 07:58:32 UTC
From: jo barden
Topic: 20334 Message: 20342

My take is that any conductor close to a transmitting antenna will have some level of signal induced, the value of this induced signal is dependant on many variables including the inverse square law with distance, length of conductor and also the gain of both antennas etc. etc. but truth be told I have an OCFD about 6ft away/higher from a G5RV between my house and walnut tree along with a vertical 30ft away from both. So am I going to get interaction between them all? you bet.

But my plot is approx 30x300ft so stuck with it. My own view is try it. Just ground any antennas not in use and have fun.

Subject: [ham-antennas] multipile 2M/440 cm antennas

I was told by a friend that having two VHF/UHF antennas on my roof was counter productive. I had one at the back not connected to the radio and one in the middle of the roof connected to my 857D. Its when I was having my static crashes and I wanted to know if it was my antenna, and I found out it wasn't.

My question is will it hurt to have two antennas on the roof well away from each other when one is not connected to any radio.

So what is the minimum distance you can put 2 VHF/UHF antennas apart that are mag mounts on a vehicle roof. Mine are over 4 Ft. apart and one is not connected to any radio at all. The one I normally use is like 6" from my car radio antenna and I don't have any problem hitting the repeater or repeaters that are a long way away.

Subject: RE: [ham-antennas] multipile 2M/440 cm antennas

My take is that any conductor close to a transmitting antenna will have some level of signal induced, the value of this induced signal is dependant on many variables including the inverse square law with distance, length of conductor and also the gain of both antennas etc. etc. but truth be told I have an OCFD about 6ft away/higher from a G5RV between my house and walnut tree along with a vertical 30ft away from both. So am I going to get interaction between them all? you bet.

But my plot is approx 30x300ft so stuck with it. My own view is try it. Just ground any antennas not in use and have fun.

20348. AW: [ham-antennas] adding phasing stub to 1/4 wv 2meter (mobile ant.)for 70cm dual band operation

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-29 20:42:16 UTC
From: Siegfried Jackstien
Topic: 20336 Message: 20348

The stub is added halfwave (on 70cm) up from the base
The current up and down again does cancel (like in a ladderline)
So the stub is acting like a trap
Only the lower third of the antenna is radiating on uhf (so thr plan on this type of antenna)
i could model it in mmama to say if it is right what I am guessing :-)

20349. mini horse antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-29 23:05:44 UTC
From: fly_ul
Topic: 20349 Message: 20349

On the following webpage http://hem.passagen.se/sm0dtk/ SM0DTK discusses the mini horse antenna. It states it has 10 db gain.

Has anyone built this antenna? Does anyone have a link or copy of the QST March 2010 article by SMODTK.

This looks like an antenna I would like to attempt to build.

Thanks

I drug an old butternut vertical that I had in storage out this weekend and put it up so I could get back on the air this winter after an 8 year sabbatical (working my @$$ off sabbatical?) any way everything is up and working reasonably well on most bands the 30 meter resonator had a damaged cap which I will need to replace but beyond that the SWR is below 2:1 on all bands

I have one small problem left..... the base matching coil that goes across the input to ground is MIA. Not hard to make one but I need to know the number of turns and the diameter of the coil. Could someone out there with a B-nut go out and count the number of turns and measure the diameter of their coil

Hi Dave,
    I ran out to my ant. barn and did a count on one of mine.Looks like 17 or 18 turns. I'ts been around for awhile so
 a little streched out. It's app. 1 & 1/2 inch in dia.
   Hope this gets you in the ball park.

Dave,
I looked at the pdf manual on their site and saw no coil for matching.
I did see where they asked for 2 chokes about 8 feet apart
I only have the 4BTV and I sent for the direct coax feed bracket.
I'm antenna restricted so I take it down in 2 sections and then clamp it to
a pipe next to the lake.
I never use any radials and all 4 bands are below 1.5 or better.

Bob

Not sure what you were looking at but that was the other thing I couldn't find after 8 years was the manual . so I downloaded a copy of the manual from the Butternut Web site and the coil is shown in the parts list," ITEM Q, Base Matching Coil" ., of course no indication of the size or number of turns,.....Mark W8GY put me in the ball park at 18 turns 1.5" diameter. I don't think it is critical as I recall you could mangle the thing and the SWR did not change much

I have a used butternut vertical (not on the air yet as it it in bad condx) and I think the coil
is not for matching, I think it is a static drain choke. The coaxial stub is for matching.

Ron

As I vaguely recall it offsets some of the reactance of the 75 ohm coax section (on some of the other bands besides 20) On 20M it is essentailly a 1/4 wave section ...AND ... it is listed in the parts list as a "BASE MATCHING COIL" ...????

I'll let you know the actual results when I get it would and installed .....

Let me know If I can help you with your B-nut ... I have a few parts from a scavenged HF6V sitting here as well at one time I was going to put up a pair of them to feed in phased array fashion ... I think I have had my original HF6V almost 30 years now :-)

20367. Re: Help with Butternut HF6V

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-30 16:06:05 UTC
From: AB2ZY
Topic: 20350 Message: 20367

There is a Butternut Yahoo group.

All the Butternut verticals use a few uH coil at the base to increase the impedance on 80m, which will be low with a decent ground radial system owing to its short radiator length and thus low radiation resistance.

On the HF6 and HF9 there is a quarter wave (on 20m) 75 ohm matching stub which is used to tranform the 100 ohm or so feedpoint impedance on 20m down to 50 ohms. On the other bands it is relatively invisible.

20368. Window/door feed-thru jumper

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-10-30 16:42:59 UTC
From: kj4fgi
Topic: 20368 Message: 20368

I soldered together a Window/door feed-thru jumper with 450 ohm Ladder Line and 2 SO-239 chassis female connectors. I got the idea from the Comet CTC-50M, I put it in between my Sliding Glass Door and shut it. I built a long wire antenna and a 9:1 balun out of t130-2 toroid. I trimmed the wire for 10 meters (1 wavelength not half) The antenna is about 11 feet off the ground over Florida ground (Sand)

I'm using an Icom Ic-706MKIIG, I made contact with Belgium, Germany and Trinidad. My question is the Window/door feed-thru jumper with 450 ohm Ladder Line and 2 SO-239 chassis female connectors through the metal sliding glass doors, does that do anything to my signal? Increase impermanence?

I can't drill any more holes through the house 4 was enough, before she hits my over the head with a Rolling Pin.

Ed KJ4FGI

The "metal sliding glass doors" will create a serious low impedance bump in impedance in the
transmission line at the occurrence. I wouldn't worry about that, I would cover the line with at
least two layers (on each side - wrap it) with black electrical tape to prevent insulation damage
and increase the insulation thickness. Look for another, better way to get the cable out.

Is the door aluminum or vinyl?

It will cause an impedance bump in the line which will have to be tuned out. Beyond that, probably not anything significant beyond possibly increased noise pickup.

If it is a metal door and you were at a high voltage node or running high power, it could possibly arc over to the metal door.

If the ladder line is solid conductor, I would also watch to make sure that the conductors do not break where they go through the door (over time).

I'm bringing in my twin lead the same way, but through a vinyl window (but I'm not using coax, the twin lead goes all the way to the dipole.)

From: studentofradio
Topic: 20371 Message: 20371

I have a G5RV Jr that is resting on the top ridge of my house for now. It's in a perfectly straight line with the roof shingles directly beneath and in contact with the antenna wire. Some day I'll figure out a way to string it up higher, but it's been working fine while I learn the basics of ham radio - I've reached as far as Russia with my Yaesu FT-897 putting out 100 watts (not sure how much goes out the antenna.)

It snowed yesterday here in New Jersey - we got about 4 inches of the stuff. When I tried to use the radio on 10 and 20 meters, which has an LDG AT-897 Plus antenna tuner attached, it took the tuner alot of time to tune - much more than the usual couple of seconds. Does the snow have anything to do with the long tuning time (10-20 seconds)?

Thanks, Dave WG2R

Yep. They sure do. In a Nova Scotia ice storm an 11 element 2 meter beam typically turns into an off-resonant driven element between a bunch of reflectors. Basically, snow and ice lower the resonant frequency.

Thanks Siegfried and Dave for the help. Siegfried - right now I'm getting away with just letting the antenna wire lie on the roof's peak, but I like your idea of some short standoffs. The house is about 60 feet long, hence my choice and purchase of the G5RV Jr, which is about 53 feet. Eventually I'll get a power meter and know better.

Interesting.....

Just this past week I raised my 20M dipole to 25 feet. Construction is of 14 gauge stranded wire that is insulated. Center and end insulators are small lengths of 3/4 PVC.

SWR at 14.250 MHz is about 1.25:1. HOWEVER, this saturday night here in Maine we had a snow storm (wet snow). I saw my SWR creep up to 2.4:1 during the storm. By today it was back to 1.25:1 as expected.

My theories are one or more of the following.....

End insulators are too short (about 2 1/2 inches) and were bridged somewhat by the wet snow.
Wet snow on the antenna detuned it.
Wet coax connections - not likely since all was checked and wrapped 4 days ago.

Your first two hypotheses are probably correct. Also, the center insulator can be bridged by ice, which will affect the impedance. I have an MFJ 102-ft doublet, and the impedance changed when it rains. I may need to cover the center insulator to keep it drier.

Frank

If you are talking the MFJ1777 all band doublet the problem is not the center insulator but likely the 450 ohm ladder / window feed line itself. The problem with the plastic window lines is that water (or snow & ice) on the surface of the line changes the dielectric constant of the line slightly which in turns changes the characteristic impeadance of the line which in turns changes the match to the antenna. If you using a tuner then you have to retune. The problem gets worse as the line gets older, tiny cracks and dirt on the line trap more water. Water tends to bead up and be less of a problem when the line is new. I tried making phasing stubs using the stuff and it was great as long as the wx was dry ..but the first sign of rain and the stubs detuned (lower in freq) . In my case I went to true open wire line and it solved the moisture sensitivity. I have often wondered if you wiped the window line periodically with something like Amour-All if that would reduce the moisture accumulation (facilitate water beading)

Dave,

You're right; good observation. I didn't even think about the ladder line. Two square inches of center insulation is negligible compared with 60 feet of ladder line. I like your idea of Armor-All. I'll try that next time I lower the antenna.

Ah ha! I knew there was some reason I preferred real open wire vs. ladder line!

The universal acceptance of ladder line was beginning to make me think that it was just as good as the real stuff ;-)

Nothing inherently wrong with Window line if you are using it as a feed
line with a tuner , you just have to remeber that you may have to retune
when it rains. If you are trying to use the stuff as an impedance
matching stub in a non tunable system however different story. Window
line is physically better behaved than open wire line in most applications

Check out Tractor Supply. I bought electric fence poles which are gray fiberglass rods about 3' long and approx. 3/8" diameter and they were very reasonable at a little over $1.00 each.

Also, Farm Tek has different sizes of similar poles in their catalog.

I have heard that 600 ohm is more resistant to detuning. Any truth to that?
Any other advantage of 600 besides slightly lower loss?
I'd like to possibly change my 300 to 450 or 600.

Thanks

I would think the end insulators would be much more sensitive to moisture than the center insulator because of the impedance present.

I just used a Cabella's Crappie Pole to suspend my flex j-pole about 15ft high. These are pretty cheap. Of course there are lots of different fishing rod blanks so perhaps if the OP gives a bit more detail on what the required specs are someone can may know a source. The light hollow pole I used is quite different from a solid rod. Both useful but not for the same thing :)

IF you are talking true open wire line in each case then the loss differences at HF are not enough to talk about

300 ohm tv ribbon line has about .5dB /100 ft loss on 10merters and less as you go down in freq
450 Ohm Window line has about .15db/100ft on 10M
600 Ohm open wire line about .1db/100ft on 10M

Source : Arrl Antenna Handbook

so you can see maybe on a 200 ft run the you gain about 1dB from 300 ohm TV ribbon to 600 ohm open line(can you hear the difference?) and certainly purely based on loss not enough difference between 450 ohm window line and 600 ohm open wire to talk about

Tuning stability is another matter

The higher impedance the transmission line, the higher the Voltage and the lower the current, the
lower the loss which is from I X R loss (from lower current) in the wire and the more it is effected
by nearby objects and the more tolerant the antenna system will be to "off frequency" operation.

Yes. The only trouble is the end feed will be a high inpedance not matching
the 50 ohm coax feedline.
Will have to have use a match box or tapped coil arangement. I think the
tap goes to 50 ohm coax center conductor and the end goes to the antenna.
The other end of the coil is the common ground.

From: Frank Kirschner
Topic: 20371 Message: 20391

That would be true for a resonant, half-wave dipole, but I'm not sure it holds for a non-resonant doublet like mine. The impedance at the feed point varies considerably with frequency, and is the hardest to tune on 15 meters. It is quite high on that band. And 15 is the band on which I notice the most difference when it rains. On 20 meters, for which the 102-ft length is selected, rain has no effect.

So I'm guessing the effect you mention applies at 20 meters, not so much at 15, and somewhere in between on other bands.

20392. Snow's Effect on Vertical Antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-01 16:13:08 UTC
From: James
Topic: 20371 Message: 20392

Hi...

Dave, WG2R, has brought up an interesting subject. I've often seen the slight changes of tuning on horizontal antennas from snow and rain... but they have been temporary effects. Most often, they are gone in a couple of hours, or at most, a day.

I have a trap vertical sitting on a 36 x 66ft radial field, and am curious as to the operation of the field when covered with snow. Most articles I've read cover "rain" operation with comments about "improved operation", but no studies that I've found, mention operations when snow covered.

First, a couple of comments:

One, there can be snow on the ground here in Southern Wisconsin four or five months of the year, ranging in depth from a couple of inches to a couple of feet. Once the "big stuff" gets here, it won't be gone till springtime. Does it help or hinder vertical antenna operations? And by how much?

Two, my impression of operating a vertical in the winter time has been outstanding. Yes, I've got a good radial field in good soil, and 99 percent of my operations are in the winter, but the ground is also frozen to a depth of three feet or so. Power output is generally in the 5w/50w, or sometimes 10w/100w, range, but my antenna is also 160ft away from station.

The snow doesn't help with the vertical's notorious "skip" zones, so I've purchased a couple of Reyco traps from Unadilla and will use those to convert parts of the vertical into an inverted "L" on 40 and 80 meters. (They do sell them separately, you just have to ask.) Hopefully, this winter I'll have a "local" qso, or two.

Aside from my "story", I don't know how snow or frozen ground effects the operation of my vertical antenna, if any. No models, studies, or comments have come to my attention.

Any thoughts appreciated.

Jim, K9JFK

Some day I'll figure out a way to string it up higher, but it's been working fine while I learn the basics of ham radio - I've reached as far as Russia with my Yaesu FT-897 putting out 100 watts (not sure how much goes out the antenna.)
>
> It snowed yesterday here in New Jersey - we got about 4 inches of the stuff. When I tried to use the radio on 10 and 20 meters, which has an LDG AT-897 Plus antenna tuner attached, it took the tuner alot of time to tune - much more than the usual couple of seconds. Does

the snow have anything to do with the long tuning time (10-20 seconds)?

Subject: [ham-antennas] Snow's Effect on Vertical Antennas

Hi...

Dave, WG2R, has brought up an interesting subject. I've often seen the slight changes of tuning on horizontal antennas from snow and rain... but they have been temporary effects. Most often, they are gone in a couple of hours, or at most, a day.

I have a trap vertical sitting on a 36 x 66ft radial field, and am curious as to the operation of the field when covered with snow. Most articles I've read cover "rain" operation with comments about "improved operation", but no studies that I've found, mention operations when snow covered.

First, a couple of comments:

One, there can be snow on the ground here in Southern Wisconsin four or five months of the year, ranging in depth from a couple of inches to a couple of feet. Once the "big stuff" gets here, it won't be gone till springtime. Does it help or hinder vertical antenna operations? And by how much?

Two, my impression of operating a vertical in the winter time has been outstanding. Yes, I've got a good radial field in good soil, and 99 percent of my operations are in the winter, but the ground is also frozen to a depth of three feet or so. Power output is generally in the 5w/50w, or sometimes 10w/100w, range, but my antenna is also 160ft away from station.

The snow doesn't help with the vertical's notorious "skip" zones, so I've purchased a couple of Reyco traps from Unadilla and will use those to convert parts of the vertical into an inverted "L" on 40 and 80 meters. (They do sell them separately, you just have to ask.) Hopefully, this winter I'll have a "local" qso, or two.

Aside from my "story", I don't know how snow or frozen ground effects the operation of my vertical antenna, if any. No models, studies, or comments have come to my attention.

Any thoughts appreciated.

Some day I'll figure out a way to string it up higher, but it's been working fine while I learn the basics of ham radio - I've reached as far as Russia with my Yaesu FT-897 putting out 100 watts (not sure how much goes out the antenna.)
>
> It snowed yesterday here in New Jersey - we got about 4 inches of the stuff. When I tried to use the radio on 10 and 20 meters, which has an LDG AT-897 Plus antenna tuner attached, it took the tuner alot of time to tune - much more than the usual couple of seconds. Does the snow have anything to do with the long tuning time (10-20 seconds)?

In general, the condition of the soil under radials on the ground is of little consequence. A proper radial field is a screen that isolates the radiator from the soil.

Where soil conditions matter more is in the fresenel zone and far field.

I am afraid I disagree with you Al

I made one as per AA5TB and the G0KYA article in Radcom and in all honesty it was easy, now I grant you the LDG Z11 pro11 is an excellent bit of kit but it tunes it from 14mhz through to 28mhz but the antenna was made to 17m dimensions. It was made out of crappie fishing pole with enamelled copper wire up the inside and impedance transformer in waterproof box with the winding on an 140 ferrite (red). Using my FT-450 and max 100w it has got me JA,LU,ZS,PY,YC and Alaska so I am not complaining. Saying all this the bands are improving so that is probably helping a lot along with lower power but more efficient modes eg. RTTY/PSK/CW as well as 100w SSB.

The pole is one of them tapering ones so I have taped the joints to stop any movement, if you can access the Radcom archive for October 2010 that is when G0KYA did article on construction but if not AA5TB's web site is just as informative.

Subject: [ham-antennas] Re: Feeding a Half-Wave End Fed Antenna

With a half wavelength you will need a matching network as the impedence will be a few thousand ohms. You lose the ability to run much power due to the very high voltage the matching network will be subject to. Evan 100W is likely to cause issues with modestly rated components. And the matching network is likely to render the antenna a monobander.

Unless there is a compelling reason to feed the antenna at the end (e.g., portable operation), most people would be better off configuring that half wavelength wire as a dipole.

Or use a counterpoise of some sort...

Verticals tend to shed snow and ice. They are only apt to detune if
they get coated in an ice storm.

I think you should log your receive level ("S" meter readings) from several HF stations, such as
WWV and CHU (if they are still operating) and any HF beacons that you can hear and see if their
signals go up or down with weather. (starting now)

Too many variables involved besides just weather to conclude anything
from this type of data collection :-)

Topic: 20401 Message: 20402

IF your question is in regards to some local zoning ordinance it depends on a couple of things.

1) If the ordinance says "TOWER" heights shall not exceed say 50' this is generally interpreted to mean the tower plus the mast. So technically you could put a 30' vertical antenna on top of 50' tower and still meet the local code.
2) If the ordinance says "ANTENNA" height then that includes the tower and PLUS the antenna
3) Going back to #1 for a minute , even though the code says "TOWER", if in a poorly litigated prior case it was argued and the judge agreed that the intent was "Tower+Antenna" then that sets a precedence by which subsequent cases can be argued (and you loose) . Bad precedences can be overturned on appeal, but the cost in both real money and personal time becomes a hassle.

The short answer is it depends :-)

Good luck
Dave

Hey Guys,
If you move to the West coast of Florida where I am, the snow accumulation is not an issue. We don't use heating oil and I think my heat strips on the air conditioner came on for less than an entire week last winter. Unless you use air conditioning in the summer time, the electric bills are less then $40 per month to run the water heater,refridgerator and fans..I pay $6 for two light bulbs, per month when I am away. There are many downsides but with the weather so great lately, I can't think of one.
I even have a condo for sale your will love. In back of a great shopping centre you can walk to not even a block to the best grocery store in Florida, Publix. Seriously call me it interested. Taxes are also low with $25,000 homestead exemption and other discounts you may pay $100 a year max or maybe less.
Come on down, the weather is great and the 10 15 meter bands are wide open.
Await your reply,
George Collier 813 238 4830

20404. Re: tower height

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-02 18:10:34 UTC
From: Bryan
Topic: 20401 Message: 20404

When it came time to submit the permit application for my 72' tower, I asked if the height is the overall height or just the height of the tower. Initially, I intend to install a Force 12 C-4XL 40/20/15/10m yagi that requires boom support. The mast will extend 10' above the yagi. I also intend to install a Cushcraft AR-10 on top of the mast. That puts the highest point at 72+10+16 = 98 feet AGL. However, the county was concerned only about the height of the tower itself. Your mileage may vary.

Ask the people who will be issuing your permit or your PE. It's their job to answer those questions for YOUR application. Anything else is just speculation and can lead to disappointment (or worse).

20405. Advice on spacing - HF bean to 2m beam

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-03 03:33:44 UTC
From: ve9xyz
Topic: 20405 Message: 20405

I am installing a Mosley TA-33-M-WARC beam on a 32' self-support tower, and am womdering about the required spacing between that HF beam (mounted horizontally, of course) and my 13 element Cuscraft 2-meter yagi, which I plan to mount above the Mosley, in a vertical yagi configuration.

I'm not sure what spscing I need to ensure that these antennas both work properly.

Can someone with some experience with this advise?

Thanks,

Kevin

Your math leaves a little to yet figure . A 50 ft. wide lot with the tower in the center would be 25 ft from each side . This would make the maximize antenna height appox . 16ft or 2/3 of 25ft. ... Good DX Chuck Wq5B

Joe,

That would appear to mean that if your tower is 50 feet tall, it has to be at least 75 feet from any property line.

If you have a 50 foot wide lot, that would appear to limit the height of your antenna to (50/3)x 2 = approx. 32 feet.

Of course, I could be wrong. But that is what it seems to say.

Going through the local tower ordnance it states the below. What do you all think it means/

(3) Amateur radio. This ordinance shall not govern the installation of any tower or antenna support structure that is owned and/or operated by a federally licensed amateur radio operator, that is less than 75 feet in height and is placed at a distance equal to or more than one and one-half the height of the tower from any adjacent property line.

From: kj4fgi
Topic: 20368 Message: 20407

Thank you for all your help, sorry for not getting back so quick, got sick. I am only running 100w of power at the most and the door is aluminum and the wire is solid and the door insulation is a little of a buffer. The Ladder Line goes through the side of the sliding glass door that I don't use so once I shut it that's it.

I am thinking of making one more feed through, I like experimenting with long wire antennas and unun/balun, I live within a HOA and "no antennas visible from the road" law is in effect. I have woods behind me and I have a few pulleys about 13 feet off the ground (the high point of my house) to raise and lower my antennas for easy experimentation, also the sliding glass doors are in a covered patio (Lani) as they call it hear in Florida and it keeps the connectors out of the elements. Again, Thanks for the answers as my knowledge is only from asking questions.

I got a piece of wood that would fit in the track snug about 4 inches wide. I put it in and drilled holes thru it for my 2 inch barrel connectors. My doors and windows are also aluminum but I’m using coax not wire.

Looking for instructions on building Hex Beam Antenna that could be set up in the field for such purposes as Field Day, or other emergency operations.
Basicly a three band HF type.
1. Where can I find the parts, design, ect.
plus any personal information on this type of antenna that you may have built.

Thanks,
de N5DRG

20410. Re: Window/door feed-thru jumper

From: kj4fgi
Topic: 20368 Message: 20410

I was reading about using the window project, the type of windows (builders special) are cemented into cinder block so the holes would be very shallow and not continuing to keep a home safe environment. My idea was to replicate the $59.00 Comet CTC-50M Window/Door Feed-Through, I figured the only thin different is they probably use a more flexible/stronger conductor than ladder line for mutable open and closures I will do it once or twice and that's it.

If the SWR goes up and it turns out to be the feed through I just solder an new 12 inch length of ladder line. Thanks for the suggestions, I appreciate the response.

You could start with the hexbeam homebrew page:

http://www.midcoast.com/~w1gql/hex/hexbeam.htm

by W1GQL.

Here's another useful site:

http://leoshoemaker.com/hexbeambyk4kio/general.html

A Google search for "hexbeam" will bring up these and other sites.

Ever heard of the "spiderbeam?!?
http://www.spiderbeam.com/
Nearly the same thing ... but easier to build (only 4 spreaders instead of 6) ... there are "kits" available with all needed parts
Or you can just use the building instructions and build it from other parts (fishing rods etc.)
Many dx-peditions use this antenna (and they know why)

20420. Re: Feeding a Half-Wave End Fed Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-05 04:19:01 UTC
From: kj4fgi
Topic: 20190 Message: 20420

I have a PAR end fed for 20m and 40m, I wound an T130-2 Toroid and made an End Fed for 40m antenna from emergency amateur radio club
http://www.earchi.org/92011endfedfiles/Endfed6_40.pdf

Now while listening on 40m I switched between the one I built and the PAR (fyi Par on e-ham got a 5 on all 342 reviews) the Par antenna gave a good signal with low noise , mine gave a good signal more noise I than switched to another Longwire antenna which uses a 9:1 balun with ground radials an increased noise, the Par antenna very low noise.

What is it in the Par single wire,no ground end fed that makes it so good. When HF conditions are real good I can get a qso with Australia and fair conditions no problem with Europe. My antenna is only 12 to 13 feet above lossey soil (Florida Sand)

While the PRB-1 is a law about Amateur Radio and being able to use them without restrictions by lower government officials.
The First Amendment of the Constitution has nothing to do with this.
Putting up a tower and Freedom of Speech are two separate issues.
Not unless you are talking about “petition the Government for a redress of grievances.”
That might have something to do with it but I really doubt it.

Just a Thought.

It's not about the tower. It's about the ability to use it.
Tower ordinances and alike are most likely a matter of aesthetics ans
safe installations.
PRB-1 and Part 25, sec104 is about the right the the licencee to utilize
his/her installations over and beyond the authority of governmental
bodies below the Federal Communication Commission. And therefore, it is
my right to access the airwaves under the 1st amendment with the license
privileges issued to me by the FCC.
Now, one can jam it down their throats or spoon feed it gently.

You'll never get the First Amendment on the plate if you take it to court. The First Amendment has nothing to do with your tower or the Use of the Tower for Amateur Radio. The first Amendment is about Freedom of Speech, Religious rights and Grievances. I see nothing there that says "Use this for Amateur Radio."
The FCC LAW is what gives you the right. Not the Constitution. Until the law was written you would not have a leg to sand on.

Amendment I

Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the Government for a redress of grievances.

Don't see anything here about Amateur Radio.

Now it does give you the right to speak your opinion and that the Government does not have the right to Establish a Religion and they do not have the right to keep you from practicing your religion.. It also gives you the right to assemble peacefully and that you have the right to Petition the Government with any grievances that you have against the Government.

I for the life of me can see nothing here that protects your rights about your Amateur Radio

Again just a thought

Topic: 20196 Message: 20426

This all sounds good and all that. but i see one Loophole on their part. Here is the ord again,

(3) Amateur radio. This ordinance shall not govern the installation of any tower or antenna support structure that is owned and/or operated by a federally licensed amateur radio operator, that is less than 75 feet in height and is placed at a distance equal to or more than one and one-half the height of the tower from any adjacent property line.

No where are they saying anything about stopping me from putting up a 75 foot or less height of tower. But what i see is crazy is the 1.5 height vs distance from any property line. like a tower can jump 1.5 it's height so it can fall outside the property.

In the USA a typical suburban "Lot" (wiki referenced) is 85 feet wide and 115 feet deep. With this ord even if someone was to put the tower in the dead center of the property, the max tower one could put up is only a little over 26 feet tall!! What a Joke!

But I can see their loophole. All thay would have to say to this restriction is, well you can put up a 75 foot tall one without getting our permission,, all you haveto do is buy a lot of land somewhere so it fits in with the 1.5 the height format! you would have to have a lot that was over 220 seet on a side more than an acre.

From: Richard Schmuke
Topic: 20425 Message: 20427

I have not had any experience with store bought centers but a piece of scrap plastic and a SO-239 you can make your own, I then added split bolts so the wire can be changed without unsoldering and resoldering. All this can be done for less than half price of store bought.

Although the Constitution was written during the forming of our Nation, the freedom of speech could be construed to include amateur radio as a form od speech in that it allows us to talk around the world. The freedom of speech doesn't end just because a new form of transmitting that speech has been developed, Freedo to apply that speech is to EVERY FORM.... So it could include such things as towers which enables the ability to use this particular method of transmitting speech....

I am sorry but the Constitution would never be a way to back up your claim. Just won't hold water. You don't need a tower to talk on a Ham Radio. Hence you still can practice your so called Free Speech. However you are still very limited depending on how close you live to an Airport. In that case the Freedom Of Speech won't even keep up with your claim.
While the First Amendment does protect your right to Freedom of Speech the Rules of Amateur Radio limits your Freedom of Speech by what you may say while you are broadcasting. There are certain things you can and can not do. But that is beside the point. The First Amendment has never been successfully used to establish someone's right to put up a tower or antenna. You could try but I am really afraid you would get laughed out of the courtroom. You might get a nice try. But that would be about all. If the first amendment protected your right to the tower then the law written by the FCC would not be necessary. So there again you shoot the first amendment down. Nice try.

I now really thing that we should go on to other things. We have beat this horse to death so to speak. Nice subject and it would be nice if it were that easy but it never seems to be. You would think that by now all States and Local Governments would know about this law. I can see that maybe a Bunch of People with a Housing Authority or whatever might not know about this but it seems that somewhere in there a lawyer had to be in there somewhere or the things they restrict residents would be struck down as the are not City Ordinances. Which it seems a lot of Cities don't even know about the Law. I think maybe someone should start sending this out to all the different cities (I know that is a lot but it could stop a lot of this stuff happening and then it would be a no brainer) so that they know that you can't do this.

Again. It is just a Though.

What the ordinance does is set the parameters whereby you do not need a special use permit. You can go to the building department and they must issue you a building permit as long as the project is within the limits set forth in the ordinance.

The limit of 1.5 times the height is physics defying, but quite predictable as an imagined safety margin when an ordinance is written by non engineers. You can apply for a zoning variance or a special use permit, which would be similar to what you would have to do to build, say, a structure outside the setback limits.

If I were on the ZBA, I would not look kindly on a proposal to build a tower whose height is such that it could fall on a neighbors _occupied_ structure. Simply falling on anothers property or unoccupied structure, e.g. a garden shed, could be addressed with appropriate insurance.

If you're going to go down this road, purchasing Fred Hopengartens's book is a prerequisite: http://www.amazon.com/Antenna-Zoning-Amateur-Fred-Hopengarten/dp/0872598217

> set of guys at the top? It'll be secured to the house at about 8 feet.

A 30' three section pushup pole (28 feet) can be raised by as many people it takes to lift the
weight of what all is mounted on the pole. If there's just a pulley and rope one normal person can
do it alone, it may take a second person (or a clamp) to hold the pole vertical while you go up the
step ladder and slide up the inner (third) section and secure it to the top of the second (center)
section (with it's pin) and then to raise up that section (and the section above it) and secure it
with it's pin.
The pins are in a bag in the bottom of the bottom section.

Go ahead and break new ground, and tell us how that turns out.
That's not how they are normally installed.
All it takes is one pulley and possibly a cleat.

20438. "Miracle Antenna MMD" dipole for sale

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-05 22:35:54 UTC
From: Neil
Topic: 20438 Message: 20438

I have a new "Miracle Antenna Mixed Mode Dipole", 40 meters for sale. Used it for 4 days but I found that since my homeowners association required me to hide the antenna just 4 feet off the ground I was limited in DX. Worked perfectly for contacts here on the west coast.

The product web site is:
http://miracleantenna.com/shop-products/shortwave/52-miracle-mixed-mode-dipole

Also check the reviews on eham.net at:
http://www.eham.net/reviews/detail/9006

New antenna costs $130 + shipping. I will sell it for $100 shipped by priority mail, (or best offer).

Hi N5DRG....

If your interested in hexbeams, join the yahoo hexbeam group. Very active and full of people building, using, modeling, and developing hexbeams. I'm working on one, but won't have it running and up until next Spring... too much else to do right now. Cold weather and snow will soon close my project for the next 4 months.

Go ahead and show the HOA that you can be compliant. Mount it two feet off the ground. Fire up a kw linear and your keyer and let them use it for a limbo line. The new and improved Herky Jerkie Limbo Dance. There are too many HOA's with Presidents named Moe and officers named Ron.

I have an old lafayette cb which has an antenna which is over 58 inches and a pair for rabbit ear tv antennas. Can I use one of the ear and the cb antenna to make a 2m jpole ?

Thanks
Hal w4hal

It is possible, depending on how you use it
Now, if the CB antenna has a loading coil of any kind, it then
becaomes a problem.

57.70 inches would be the length for the taller element, and 19.33
for the shorter element. One would be grounded to a bar or angle iron,
the other fed direct from the center of the coaxial cable with the
shield conencting to the bar, which can be clamped to a mast.
The J Pole is basically a half wave zepp with a 1/4 wave feedline.
Or, you could use both element on the rabbit ears, one set for one
quarter wave length and the other for the 3/4 wave element, with
spacing between them of 1 to about 3", depeding
One drawback I see it maintaining the proper length of the elements,
and another is in mounting.
You need to figure out these factors.

Good luck

Wayne WA2YNE

See my photos at:

http://groups.yahoo.com/group/ham-antennas/photos/album/754766111/pic/list

Use (285 X .75)/f for the long pipe.

Use (285 X .25)/f for the short pipe.

Remember the "zero Ohms" point is at the center of the short.

There have been many attempts to eliminate the need for a balun but NONE of them work.

20451. PL-259's Silver Plates vs Nickel Plates and teflon centers + coax seal

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-08 05:37:59 UTC
From: pchapman920
Topic: 20451 Message: 20451

With a number of new members etc and maybe some new hams who do not know yet, just thought I would pass this along. Do not buy just any 259 to build your antennas. Always get silver plated parts, which are hard to find at a local store that sells said parts. I do not know why, as they can be found pretty reasonable at Hamfests and online. Hamfest prices at the Stone Mountain (Atlanta Area) Hamfest this past weekend for silver plates with Teflon interior were $19-$22 for 10 or more and the reducers for RG8X were $4.50 to $5.50 for 10 or more......about $2.50 each. Even with extreme clean and care, nickel plates can not hold a candle to the bond you get with a silver plate connector.

Just thought I would also repeat a tip from someone here. If using coax sealer or tape etc.....someone here suggested using teflon plumbing tape as an undercoat, then top with electrical tape etc....great suggestion for antennas that have to go up and down, like here. No goo to fool with and great easy adhesion with the silver plating.

I have never had a problem soldering to the nickle plate ones , just takes heat and the right flux , the hard part is not melting the centre insulation . just for kicks one day I put one together with RG8 and prepared the coax in the usual way and left the outer insulation a bit long and screwed it into the connector and did not solder it (I know what some are going to say) I hope it does not stir up a hornets nest . anyway I just solder the centre conductor to the pin and assemble it . have not had any problems with them yet , been doing it for 5 years now . I do the same with the RG8X , fold the braid back over the reducer and run it in tight , no solder .

I do use Silver but if I get a good deal on Nickle Plated I use a Dremal to rough up the surface, removes the Nickle Plating easy, using a small grinding stone, a brass color appears, solders real good and solder as usual no high heat needed.

I do the same, use a small square file and rough up the holes and good to go after that, and I do fold the shield over the reducer then solder.

Let me add a note to Fred's idea. When working with a coax fitting I often slip a mating fitting on it to act as heat sink and/or a help holding the center pin in location. I find this almost a necessity when making a SO-239 into a antenna 1/4wl 2m antenna. See http://i1102.photobucket.com/albums/g453/KD0ZZ/DSC00811.jpg

Rich, Kd0zz

Topic: 20409 Message: 20456

Hi Danny...

There are two types of hexbeams. The first is called "Classic", developed by Mike Traffie back about 10 years ago... both the driven and reflector elements have the "W" shape.

Along came cheap and powerful modeling programs....the broadband HEX was developed through modeling by Steve, G3TXQ. The advantage of the "broadband" is better swr at the band edges. The shape of the driven element is still the "W", but the shape of the reflector is a "U". All of the G3TXQ broadband information has been published on his site at... http://karinya.net/g3txq/hexbeam

Both types are good five or six band rotatable antennas; the Broadband version gives you better swr at the edges, but the Classic gives you a smaller footprint. Both can be mounted and turned with a very modest setup because they are light, about 20 pounds, and symmetrical.

There are also some "plug and play" hexbeam versions, but the antenna lends itself to homebrew construction. Besides suppliers for parts, there are also a couple of "kit" versions available.

Most hexbeams cover the 5 bands from 20 to 10m, and maybe 6m, but there have been several 40m/30m versions built. Its doable because they can still be rotated, but you need sturdier equipment.

That about covers the 25 cent tour of the hexbeam, except for the reviews. Check out eham.net.

I have never had a problem soldering to the nickle plate ones , just takes heat and the right flux , the hard part is not melting the centre insulation . just for kicks one day I put one together with RG8 and prepared the coax in the usual way and left the outer insulation a bit long and screwed it into the connector and did not solder it (I know what some are going to say) I hope it does not stir up a hornets nest . anyway I just solder the centre conductor to the pin and assemble it . have not had any problems with them yet , been doing it for 5 years now . I do the same with the RG8X , fold the braid back over the reducer and run it in tight , no solder .

Hey guys I have a weird problem, I made a 2 meter vertical dipole, it's 20in x 20in 3/4in copper tube with a 1/4in spacer all of this is in a 1in/3ft PVC pipe. The coax is ran though the ground side and out a hole of the spacer and PVC. Sheet screws are drilled into the PVC and copper for the connections. Here is where it gets weird, the swr bounces around(yes if you let it sit on one freq it bounces) 2.3 60 ohm at both ends of the 2m freq now if I touch the coax the swr goes down to 1.8 with an ohm of 80, if I lower the antenna to the ground it also does down but doesn't bounce!
What could it be?

Sounds like a great idea but doesn't the feedline have to come out at right angles from it to be a true balanced dipole? Soundl like it's acting like a ground plane with the "radials" collapsed to the copper tube. Should make it less than 30 ohms I think. Should work, though. Maybe the coax flexes inside causing the ground plane to move around changing the impedance.

What are you checking SWR with a antenna analyzer or a 2m rig and a meter? If under power you are getting RF back down the feed line. When I make a J-Pole or a Slim-Jim I use a small line like RG-8X and go down the mast about 1/4wl then have a RF choke of 5 tight turns of coax. Then I have a chassis single hole mount SO-239 with a hood.
http://i1102.photobucket.com/albums/g453/KD0ZZ/239006.jpg

This gives me a attach point for RG-8 or 213.

If this does not work good enough you might have to add a decoupling stub.

I like the looks of the set up, yours sound nice with 3/4 copper. Please keep me informed of the solution of you problem.
Not quite the same problem but I found one time that I had good reading with my MFJ but when I used my FT-2800 as I increased power the SWR increased. My problem turned out to be water in a run of Belden 9913.

Budget ham here too! At most any good size hamfest Silverplates are $20 for ten and RG8x reducers 10 for $5. The best non-amphenol brand I get from http://www.mgs4u.com/RF-adapters.htm and they are $2.30 in lots of ten or more with reducers. Beats doing all of that filing stuff, although the method works well.

Ben,
Could be you have current flowing in the shield.
Do you have a balun or coil of coax at the feed point?

Could be this would settle thing down.

Hey guys I have a weird problem, I made a 2 meter vertical dipole, it's 20in x 20in 3/4in copper tube with a 1/4in spacer all of this is in a 1in/3ft PVC pipe. The coax is ran though the ground side and out a hole of the spacer and PVC. Sheet screws are drilled into the PVC and copper for the connections. Here is where it gets weird, the swr bounces around(yes if you let it sit on one freq it bounces) 2.3 60 ohm at both ends of the 2m freq now if I touch the coax the swr goes down to 1.8 with an ohm of 80, if I lower the antenna to the ground it also does down but doesn't bounce!
What could it be?

I've done that as well, but never on a connector exposed to the elements. You can get away with it for indoor patch cables, but copper oxidizes very quickly when subject to even a tiny amount of water.

I've only done it when I didn't have access to a big Welder (aka Weller) soldering gun.

I've had excellent luck pulling the tip out of the Weller and laying the posts right on the connector body and applying the solder to the braid until hot enough to reflow.

Haven't shorted one in over 30 years. I use 63/37 rosin-core.

Hi Kevin,

You might read the info on spacing on the Directive Systems web site:
http://www.directivesystems.com/

Go to APP Notes and then read HOW TO PLAN THE INSTALLATION OF MULTIPLE VHF ANTENNAS ON ONE MAST . Although this note is about VHF antennas, the theory is the same and will help you understand the issues.

My guess, as you are changing the polarization of the VHF yagi, that it won't matter much. However, having the vertical mast go through the vertical 2M yagi will certainly mess up it's pattern, unless your mast is not metallic.

20476. RE: advice on spacing hf beam to 2 meter beam

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-09 03:24:35 UTC
From: physics1@sbcglobal.net
Topic: 20476 Message: 20476

I did exactly what you are suggesting with a moseley cl33 and a 11 element, i think, 2 meter vertically oriented beam . Spacing was less than 6 inchs. The vhf beam was aligned with its boom parallel to the cl 33 boom. I continued to work tons of dx on hf and regularly contacted springfield, mo from kansas city on 2 meters. About 160 miles when i could make contact. I would compare this to mounting a ringo over the top of a beam---quite common configuration. I think a more pressing issue would be the additional bending load exerted on the mast, and the rotator, if yoy get them too far apart. Just my thoughts and personal experience. Also the resonance curve of the beam was not changed significantly.

Read a hint in QST some time ago regarding putting a drop of 3:1 oil in the holes of the 259 body before you attempt to solder. Seems to work for me.

Just my opinion, but with the two antennas at opposite polarizations to each other, I doubt the 2m yagi will affect the Mosley much at all, being right on the Moseley's centerline...personally I'd keep them at least 2 meters or better apart...although what I found in a Google search for "stacking yagis" indicates at least 1/2 wavelength

Here's some links with info from that search:

From: wc5m
Topic: 20451 Message: 20479

Most of the problems I see with installing PL-259 connectors is due to people not using enough heat. I recommend a minimum of a 125W soldering gun. This will allow you to solder the shield and center pin quickly enough that the insulation and dielectric does not melt and the connector will not be shorted. In 29 years as a ham I've seen way too many guys try to solder a PL-259 with a 40W soldering pencil (or smaller) and by the time the connector is hot enough to melt the solder the dielectric is starting to melt. Many people also make the mistake of melting the solder directly instead of heating the connector until it is hot enough that the solder flows into the connection resulting in a cold solder joint.

The HF beam won't be affected.

However, a yagi mounted vertically on a metal mast, will experience changes in it's radiation pattern and/or gain.

Think of it this way - the driven element is behind the mast, so it will 'see' the mast as either a director, or a reflector.

The mast becomes part of the antenna. While it will still work; it won't be optimum.

I guess my response would be to put it in perspective. There
is a mechanical penalty to spacing beams 6 feet or more apart. The tower, mast, rotator configuration has to be engineered for wind load. Also is your objective to increase your signal to local repeaters and take advantage of occassional skip? Or are you going after serious vhf weak signal contesting. I would refer you to kcvhfgridbandits.com for pictures of stacked vhf arrays for serious weak signal work. E.g. look at the antennas of N0IRS and others. A single 13 element 2 meter beam by itself would be a limiting factor in this game. So compromises in mounting need to be evaluated in light of the application, not just technical details. However, if you want absolute maximum performance, then spacing becomes more important. But now you have the more serious issue of calculating bending moments, knowing what the mast strength is etc. Masts will bend and rotators will break in high wind loads if not designed properly. Anyway have fun thats what ham radio is all about.

True:

I use a flat tip 80W Weller, hot enough for me, and under $30 with two tips. Not doing the simple stuff will bite later. How many times I've seen the tip of an iron go inside the tip in direct contact with the inner conductor, instead of under it, I can't count. Another, not tinning the inner conductor before starting. Not using 259's with teflon, a mistake.

Using the right tools is vital. Use diagonal shears to cut braid, not cutters. Home Depot sells spring loaded Crescent shears for under $10. (They are not made for wire larger than 20g) Use a rotatable suction vice with a 12X12" piece of smooth glazed tile. It's a good suction base, gives you a good splatter zone, and the solder does not stick. Use a multi-ring base with a sponge for the iron. Easy to find at $5-$8. Not having a safe place to park a 900 degree iron is just plain dumb.

Leaves are down in most areas. Now go build and hang those new antennas.

Oh I suspect you are 100% right! Good soldering technique applies here and you can't do it right with a light duty pencil.

I guess I don't really understand this whole discussion, I'm still using patch cables that I made 45+ years ago before I even understood the proper way to assemble PL-259s for soldering. (But I did understand how to solder properly.)

Heat, Heat and more heat. I can solder the inner fine but the braid I cannot with my electric iron which is 100w, even tried 2 100w irons but no luck so for 15 years I doubled the braid back over sleeve if possible and screwed in, lots of tape to keep water out. Then a couple of years ago I thought I had better have another go and I can now do it. Here is how. Old fashioned large copper plumbers iron, blow torch to heat it up now braid is soldered to outside of plug. Saying all this don't do as I did and use plumbers flux. you end up with green fur instead of braid after a month or so.

Oh another thing is to file the chrome off the brass, this helps in the tinning/soldering

I use the 25ag4 top sections here, and no problem getting a tailtwister in there. Unfortunately the Tessco web site doesn't have the measurements for the opening on the 25ag2. But it does have the measurement for the 25ag4 section. So if you already have a 25ag2 section, measure the opening and compare to the measurement for the 25ag4 on the website. If they are the same, then it should fit.

had a american beauty 250 watt iron that was made in the 1930's until it burned out .
now have a weller S-100 that does not have quite enough mass to do the job .

>
> Most of the problems I see with installing PL-259 connectors is due to people not using enough heat. I recommend a minimum of a 125W soldering gun. This will allow you to solder the shield and center pin quickly enough that the insulation and dielectric does not melt and the connector will not be shorted. In 29 years as a ham I've seen way too many guys try to solder a PL-259 with a 40W soldering pencil (or smaller) and by the time the connector is hot enough to melt the solder the dielectric is starting to melt. Many people also make the mistake of melting the solder directly instead of heating the connector until it is hot enough that the solder flows into the connection resulting in a cold solder joint.

> > With a number of new members etc and maybe some new hams who do not know yet, just thought I would pass this along. Do not buy just any 259 to build your antennas. Always get silver plated parts, which are hard to find at a local store that sells said parts. I do not know why, as they can be found pretty reasonable at Hamfests and online. Hamfest prices at the Stone Mountain (Atlanta Area) Hamfest this past weekend for silver plates with Teflon interior were $19-$22 for 10 or more and the reducers for RG8X were $4.50 to $5.50 for 10 or more......about $2.50 each. Even with extreme clean and care, nickel plates can not hold a candle to the bond you get with a silver plate connector.
> >
> > Just thought I would also repeat a tip from someone here. If using coax sealer or tape etc.....someone here suggested using teflon plumbing tape as an undercoat, then top with electrical tape etc....great suggestion for antennas that have to go up and down, like here. No goo to fool with and great easy adhesion with the silver plating.

If you use a reducer, this guy shows how it takes less heat and ingenuity to just solder the braid at the end of the reducer then cut the rest of the extended braid wires off. http://www.antennex.com/hws/ws0801/reducer.html

Oh I suspect you are 100% right! Good soldering technique applies here and you can't do it right with a light duty pencil.

I guess I don't really understand this whole discussion, I'm still using patch cables that I made 45+ years ago before I even understood the proper way to assemble PL-259s for soldering. (But I did understand how to solder properly.)

The Weller I use is an 80SPGl, only 80W and hot enough for me. I use RG8X low loss double shield, so on the reducer I cut 1/4 inch skirt and fan it around evenly, put in in the vise, and hit it about three separate times while turning to prevent drip spots or cold joints. Then insert into the shell and get the tip. On silver plates it is solid and simple. Have not done much RG8 in a while, but if you measure carefully and can create equal circular pressure, create a very, very small ripple in the braid where it will meet the holes, the heat conduction will be greatly improved, assuming you had some small airspace that needed to be filled.

> Heat, Heat and more heat. I can solder the inner fine but the braid I cannot with my electric iron which is 100w, even tried 2 100w irons but no luck so for 15 years I doubled the braid back over sleeve if possible and screwed in, lots of tape to keep water out. Then a couple of years ago I thought I had better have another go and I can now do it. Here is how. Old fashioned large copper plumbers iron, blow torch to heat it up now braid is soldered to outside of plug. Saying all this don't do as I did and use plumbers flux. you end up with green fur instead of braid after a month or so.

Hi Benjamin...

A dipole is an balanced antenna when the feedline comes away from it at a right angle. If the angle of the feedline is not 90 degrees, then you need a common mode choke; they can be ferrite or a couple of turns of the feedline. For a single band 2m antenna, 4 or 5 turns should be fine.

I also have a vertical end-fed dipole, but its made entirely from coax. It hangs in the rafters, just in case I loose my outside co-linear. Take some coax, cut the outer insulation back around 21 inches, exposing the shield; then pull the shield braid back over the uncut coax. Tape the end of the braid about 20 inches away from the cut. Use the extra inch from the exposed center conductor to form a loop that will hang over a nail in the rafters. Put four or five turns in the coax below the radiator to make a common mode choke. I've made these with both 50 and 75 ohm cables... they work fine, and there is no problem with hitting all the local repeaters with a handheld. I've never put a connector on at the antenna, but only at the radio connection point.... so it's all one piece.

This type of antenna doesn't give up much, if anything, to the j-pole or ground plane....

http://www.hamradio.me/antennas/jpole-vs-coaxial-dipole-eznec-shootout.html

OK... found this on HamUniverse...

http://www.hamuniverse.com/vertbazooka.html

.... check out the picture above the mounting pole.... these are very simple antennas. I've had no problem making both "ends" of the antenna 20 inches long. The article calculates the top section at about 20 inches, and then uses a velocity factor for calculating the section of shield that slides over the coax... make no sense to me. Changes the length of that section according to the vf of coax center insulation even though the "outer" section of the shield is facing the "outer" section of itself after pulling the braid over. The VF of a transmission line has nothing to do with the outer insulation. Personally, I'd just make both lengths the same. "Tuning", if there is a problem can be done by pushing or pulling on the braid; the upper section can be shortened by making the nailing loop bigger or smaller.

My current version of this antenna is one continuous 40ft piece of RG6. And don't forget to wind a common mode choke into the transmission line after the antenna.

Also... if anyone has good explanation of why the author of the above article is using vf to correct for the shield leg of the antenna... I'm listening.

I don’t mean for you to use 21 ft of coax. Its just good diagrams of the size on the turns. Also you don’t want it so tight as to damage the coax. I use 8 to 10 inches for HF.

20501. How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 02:37:54 UTC
From: goldtr8@charter.net
Topic: 20501 Message: 20501

Dear Group
I have just installed a 160m loop antenna that is approximately 20ft high. Performance wise other than at 80m it appears to be substantially weaker than my trapped dipole which is at 30 feet, on 80 it is equal or better in performance. I define weaker by approximately 2 s units less in power and weaker TX signal reports when I have a qso with someone.

With the above stated I have taken measurements with my antenna analyzer and would like help in understanding the data. Does is suggest that the loop should be longer or shorter. Does it give insight on ground coupling as am I correct that it is to close to the ground.

Basically I have the data but I really dont know if it is telling me anything at all.

Right now I am looking into ways to raise the antenna between 30 and 40 ft, but before I take the wire down, I want to understand what the data is telling me so if I need to make other adjustments to length I can do it. I have data so just guessing on what to do next is not good engineering practice. My problem is I am a mechanical guy not an electrical guy.

Below is the data I measured with my antenna analyzer.

FRQ SWR R X
1.77 14.9 3 -41
1.80 16 3 -38
1.83 16 2 -37

20503. Re: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 03:11:27 UTC
From: goldtr8@charter.net
Topic: 20501 Message: 20503

Its is close to a circle strung from tree to tree.

Length is about 550 ft in total length. However, this is based on
purchsed lengths of wire plus the length was more ditcated by the trees
and being able to connect the ends together.

The feedline is about 60 ft of 450 ohm ladder line to a 1:1 current
balun to 25 ft of coax to the shack

Sorry I should have included this information in the first posting

20504. RE: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 03:43:53 UTC
From: jo barden
Topic: 20501 Message: 20504

I would try feeding it via a 1:9 or a 1:4 balun perhaps switched rather than your 1:1 one. I would then try again as this will give you a better impedance transformation and is easy to "knock up" in an hour or so.

20505. 2M/440 copper pipe verticle

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 04:15:29 UTC
From: Military1
Topic: 20505 Message: 20505

I saw a recent post which described and had a picture/drawing of a 2M/440 antenna which was made from two 20" lengths of copper pipe and a 1/4 wave length of PVC piping. The write up also addressed a 5 turn choke. For the life of me I can not find where that posting was. Can anyone provide the same information or direct me to the information. Thank you very much.

20508. AW: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 09:01:01 UTC
From: Siegfried Jackstien
Topic: 20501 Message: 20508

You have to use a higher ratio balun
Then this setup should work
I jave nearly the same setup (168m deltaloop fed at a corner) but I switch feedindline length for the lower bands
On fundamental and first harmonic the impedance of such a low hanging loop is lower ans the 200 ohms ... so a 1:4 does not work well
Here my solution:
Lets start with 80m
Feeding that loop with 60 feet of ladderline transforms the low impedance to higher value (quarterwave transformer) ...
Now the higher ratio balun can do its job
On 160 I just add another 20m (now a bit shorter after finetuning) and I have the same thing ... ladderline transforms low impedance up
On 40m (and above) the impedance of the loop is higher (a few hundred ohms) so the ladderline is almost matched and does not transform ... but on the lower end is that high ratio balun bringing the higher impedance back down
With that setup I can work all bands ... and many of them without any tuner needed at all!!
I had some shorter lengths of ladderline that were left over from some fieldday projects
And with these parts I tried different lengths till I found that solution

> Hi Benjamin...
>
> A dipole is an balanced antenna when the feedline comes away from it at a right angle. If the angle of the feedline is not 90 degrees, then you need a common mode choke; they can be ferrite or a couple of turns of the feedline. For a single band 2m antenna, 4 or 5 turns should be fine.
>
> I also have a vertical end-fed dipole, but its made entirely from coax. It hangs in the rafters, just in case I loose my outside co-linear. Take some coax, cut the outer insulation back around 21 inches, exposing the shield; then pull the shield braid back over the uncut coax. Tape the end of the braid about 20 inches away from the cut. Use the extra inch from the exposed center conductor to form a loop that will hang over a nail in the rafters. Put four or five turns in the coax below the radiator to make a common mode choke. I've made these with both 50 and 75 ohm cables... they work fine, and there is no problem with hitting all the local repeaters with a handheld. I've never put a connector on at the antenna, but only at the radio connection point.... so it's all one piece.
>
> This type of antenna doesn't give up much, if anything, to the j-pole or ground plane....

>
> http://www.hamuniverse.com/vertbazooka.html
>
> .... check out the picture above the mounting pole.... these are very simple antennas. I've had no problem making both "ends" of the antenna 20 inches long. The article calculates the top section at about 20 inches, and then uses a velocity factor for calculating the section of shield that slides over the coax... make no sense to me. Changes the length of that section according to the vf of coax center insulation even though the "outer" section of the shield is facing the "outer" section of itself after pulling the braid over. The VF of a transmission line has nothing to do with the outer insulation. Personally, I'd just make both lengths the same. "Tuning", if there is a problem can be done by pushing or pulling on the braid; the upper section can be shortened by making the nailing loop bigger or smaller.
>
> My current version of this antenna is one continuous 40ft piece of RG6. And don't forget to wind a common mode choke into the transmission line after the antenna.
>

the PVC and copper for the connections. Here is where it gets weird, the swr bounces around(yes if you let it sit on one freq it bounces) 2.3 60 ohm at both ends of the 2m freq now if I touch the coax the swr goes down to 1.8 with an ohm of 80, if I lower the antenna to the ground it also does down but doesn't bounce!

Thank you for the prompt response and information and links. This is what I was looking for. I wanted to build an inexpensive 2M base antenna to support a Yaesu FT-2600M I recently picked up. All the examples you pointed me too will work.
In regard to the 2M/440 verticle, what is the signifigance of the 1/4 wave PVC section and I take it that is a 1/4 wave on 2M. Being PVC, what does that section do for you? Or am I off base or missing the obvious here? Have a great day.

Not enough difference to worry about from an antenna efficiency point of view

20515. RE: AW: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 18:03:08 UTC
From: goldtr8@charter.net
Topic: 20501 Message: 20515

Hi Siegfried,

Thank you for the reply. I currently have a 1:1 balun and the antenna does work.

What I am really looking or help on is how to understand what the data that I measured is telling me. In other words is it possible to determine from the data that the loop is short or too long for 160m frequencies. Can this data be used to help explain why it is so much weaker in RX and TX than a dipole. Can the data help predict if I move it higher and leave the length alone that it would work better and tune better at 160m or other frequencies.

Maybe the whole measurement process with a loop using ladder line to a current balun to coax is not a valid thing to do.

Basically I want to try and analyze the data, then make a prediction to a change and then make the change. Right now I don't know what if anything the data is telling me and my background in test engineering is telling me that before I make changes I should be able to measure, predict, make change and verify. My problem is the predict part I don't know the math. If this were a structures problem then its P/A or load divided by the area to get stress or the square root of k/m for natural frequencies.

So I know there is math involved and now I want to learn it, but I need a direction or example to point me in the right direction.

Thanks
Don

You have to use a higher ratio balun
Then this setup should work
I jave nearly the same setup (168m deltaloop fed at a corner) but I switch
feedindline length for the lower bands
On fundamental and first harmonic the impedance of such a low hanging loop
is lower ans the 200 ohms ... so a 1:4 does not work well
Here my solution:

Lets start with 80m
Feeding that loop with 60 feet of ladderline transforms the low
impedance to
higher value (quarterwave transformer) ...
Now the higher ratio balun can do its job
On 160 I just add another 20m (now a bit shorter after finetuning) and I
have the same thing ... ladderline transforms low impedance up
On 40m (and above) the impedance of the loop is higher (a few hundred
ohms)
so the ladderline is almost matched and does not transform ... but on
the
lower end is that high ratio balun bringing the higher impedance back
down
With that setup I can work all bands ... and many of them without any
tuner
needed at all!!
I had some shorter lengths of ladderline that were left over from some
fieldday projects
And with these parts I tried different lengths till I found that
solution

Subject: [ham-antennas] difference between using a whip or hollow aluminium tubing

If I am build an antenna is there a diffence in using the wip part of a stainless steel cb antenna or hollow aluminum tubing like what is on a roof top tv antenna ?

Hal w4hal

I would use whatever one is easier for you to build the antenna with. If portable I would use SS, for use at home, whatever is simpler to work with. There might be a very slight bandwidth advantage with tubing but I don't think it would make much difference until the diameter was larger.

Hal,
If you use 1-1/4 " PVC pipe that pipe should be large enough
to wrap 5 or 6 turns on it.
I think that 1/4 is a typo

> Hi Benjamin...
>
> A dipole is an balanced antenna when the feedline comes away from it at a right angle. If the angle of the feedline is not 90 degrees, then you need a common mode choke; they can be ferrite or a couple of turns of the feedline. For a single band 2m antenna, 4 or 5 turns should be fine.
>
> I also have a vertical end-fed dipole, but its made entirely from coax. It hangs in the rafters, just in case I loose my outside co-linear. Take some coax, cut the outer insulation back around 21 inches, exposing the shield; then pull the shield braid back over the uncut coax. Tape the end of the braid about 20 inches away from the cut. Use the extra inch from the exposed center conductor to form a loop that will hang over a nail in the rafters. Put four or five turns in the coax below the radiator to make a common mode choke. I've made these with both 50 and 75 ohm cables... they work fine, and there is no problem with hitting all the local repeaters with a handheld. I've never put a connector on at the antenna, but only at the radio connection point.... so it's all one piece.

>
> http://www.hamuniverse.com/vertbazooka.html
>
> .... check out the picture above the mounting pole.... these are very simple antennas. I've had no problem making both "ends" of the antenna 20 inches long. The article calculates the top section at about 20 inches, and then uses a velocity factor for calculating the section of shield that slides over the coax... make no sense to me. Changes the length of that section according to the vf of coax center insulation even though the "outer" section of the shield is facing the "outer" section of itself after pulling the braid over. The VF of a transmission line has nothing to do with the outer insulation. Personally, I'd just make both lengths the same. "Tuning", if there is a problem can be done by pushing or pulling on the braid; the upper section can be shortened by making the nailing loop bigger or smaller.
>

> My current version of this antenna is one continuous 40ft piece of RG6. And don't forget to wind a common mode choke into the transmission line after the antenna.

The coax is ran though the ground side and out a hole of the spacer and PVC. Sheet screws are drilled into the PVC and copper for the connections. Here is where it gets weird, the swr bounces around(yes if you let it sit on one freq it bounces) 2.3 60 ohm at both ends of the 2m freq now if I touch the coax the swr goes down to 1.8 with an ohm of 80, if I lower the antenna to the ground it also does down but doesn't bounce!

20518. RE: AW: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 19:33:40 UTC
From: Richard Schmuke
Topic: 20501 Message: 20518

I take my measurements at the feed point of the loop. It is a delta. Mine is a 80M size, then tweaked to a 1:1 SWR in the middle of the 20M phone band and I use it 40 thru 10m.

I am surprised you are not resonate and 1:1 somewhere. Do you need a 4:1 balun?

I use a 4:1 duel rod current balun at the apex and RG-8 type to the rig

You might want to try a switchable 1:1/4:1 balun, that is what I use on my 135ft dipole that is feed with 450 ohm ladder line and different bands come in better at different balun settings.

Just thinking and still confused, Rich , Kd0zz

Subject: [ham-antennas] 2M/440 copper pipe verticle

I saw a recent post which described and had a picture/drawing of a 2M/440 antenna which was made from two 20" lengths of copper pipe and a 1/4 wave length of PVC piping. The write up also addressed a 5 turn choke. For the life of me I can not find where that posting was. Can anyone provide the same information or direct me to the information. Thank you very much.

Ed,

The proper way to mount this antenna on a metal roof is simple, DON"T!!!!! The J-Pole does not need a ground plane and in fact will couple with any surrounding metal objects which will degrade or change the radiation pattern. The best way to mount a J-Pole is in the clear on a non-conducting mast like wood as high as you can get it. Also recommended by many is the use of a choke to prevent common mode current flow on your coax. These are usually in the form of ferrite beads or an air(ugly)choke balun, etc. There are many posts on these, so do a search on "choke" or "common mode current"

I have a Plumbers(copper tube) J-Pole also and don't use a balun and it seems to work OK. I have never done any testing to see if a balun helps any.

Hope this helps.

20522. AW: AW: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 21:46:56 UTC
From: Siegfried Jackstien
Topic: 20501 Message: 20522

Hmm i did the tuning with cutntry :-)
Made several runs (and made an excel sheet for my notes cause I checked it
on all bands, changed a thing ... checked again ...
Finally I found a solution that fits my needs
No tuner needed on most bands ... and on the other swr is quite low ... so
even if there I need a slght tuning the losses are low
Can you add another length of ladderline easy (maybe with banana plugs for
fast switching like I do it here) ???
The problem is (or not a problem but a thing to consider) the whole setup
has to be resonant ... antenna and feedingline
And from your numbers I can see only the resonance on 80m
Why the loop is performing

The data indicates that the antenna is slightly short based on the "X"
portion going crossing zero around 2.55 MHz

I would definitely retake the measurements directly at the antenna with
out the balun before drawing any final conclusion . Baluns do not always
behave the way theory predicts

20524. AW: AW: [ham-antennas] How should I interpret swr data from my loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-10 22:00:01 UTC
From: Siegfried Jackstien
Topic: 20501 Message: 20524

First went out too early :-)
So
Why your loop is giving lower results as your dipole?
I am guessing that you made local nvis contacts to compare?
The 2wl loop has lower gain straight upwards (a hole in he pattern)
And that is the reason why on 80 it is (a bit) lower in signal as your
dipole
But can be stronger to more distant stations!
From 40m upwards the antenna is high enough to show low angle gain
Just worked with a zl2 stn yesterday on 20m
No beam on my side and only a 3 element jr on the other
100% copy over a 18000km path!
With only 50w on both sides!
On the higher bands the pattern is a bit destructed (cloverleaf pattern)
but that does not hurt
Actually I would say it is almost omni-directional on the higher bands
Sometimes when conditions change during a qso I have situations where the
signal drops down ... then I just switch to my vertical and the signal is
high again ... when the a few seconds later signal drops on the vertical I
just switch again to the loop and most of the times the signal is high again
on the loop ... that is the reson to have more antennas for the bands ....
sometimes one antenna is better and a few seconds later the other antenna
(especially on the higher bands when conditions change fast)
Try out a higher impedance balun
And try to add another length of ladderline for 160
Greetz

Yes the ladderline has to be made longer :-)

Subject: [ham-antennas] difference between using a whip or hollow aluminium
tubing

If I am build an antenna is there a diffence in using the wip part of a stainless steel cb antenna or hollow aluminum tubing like what is on a roof
top tv antenna ?

Hal w4hal

I would use whatever one is easier for you to build the antenna with. If portable I would use SS, for use at home, whatever is simpler to work with.
There might be a very slight bandwidth advantage with tubing but I don't think it would make much difference until the diameter was larger.

My cousin just gave me a 2 meter i/2 copper pipe J-pole, any recommended
way to mount on a metal roof?

True about being fatter is better, antenna that is. One of my experimental antennas was a 5 inch diameter cage vertical on 20m, it was very wide band and the complete assemble was shorter also.

Aviation hose bands, two minimum, three if you can afford that many.
(the radiator hose bands with a screw and those angled slots)

20531. [ham-antennas] Calculating Wind Load for HDBX-48

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-11 02:11:27 UTC
From: Frank Kirschner
Topic: 20531 Message: 20531

I'm trying to get a permit to put up a Rohn HDBX-48 in Montgomery County, MD. Said county requires towers to be rated at 90 mph, but Rohn's docs only go to 70 mph. I've contacted them, and they are no help. Using the fact that wind load is inversely proportional to wind velocity, it seems like it should take the load (a quad and a small 6 m Yagi). However, I don't believe the PE I'm talking with to get the signed and sealed drawings would accept that "back-of-the-envelope" calculation.

Is there a reasonable way to calculate the wind load that a PE would accept as rigorous? I've searched the Web, and everything I have found is oriented to specific towers, and doesn't lend itself to substitution of different elements.

Any help would be appreciated.

Thanks in advance.

I can confirm the dress of the cable leaving a "J" pole antenna can and does effect the tuning of
the antenna. A sleeve balun or 5 coils of feed line (air choke balun) will minimize the effects.
Always re-test the "J" pole antenna after it is mounted and the feedline is tie wrapped. (if coax)

Ok Frank I' ve got 2 Rhon Engineer books. Assuming 48 ft with 3 Rhon concrete brackets also interwoven rebar and tied and correct depth and laterals. Also level with no more than a 2 inch 10' tall mast. The wind load area in square feet is 18 with down thrust of 360 lbs. I believe that's about it for 70.7 mph (20 psf). Now if you decided to add guy wi res (3/16") you run that mph on up some. Doesn't show that here. I don't have mind guyed and have a big Hygain TH7DXX 7 ele beam with Tailtwister rotor. Did have a 3 ele Hygain 7-3 40 meter beam up but not at the same time. He needs to be convinced the you sacrificed height for a shorter tower of great strenth and the 100 mph does not apply as I did here. I did my own drawings. They don't rate this tower any higher than 70. 7 that I can see. They don't need too. You can't be compared to 6o-80' towers.

I retired from 18 yrs as a Tn. senior real estate Appraiser (Homes and Land). The old saying goes (If you can't correct them with intelligence, Baffall them with BS) If I can be of help you know the rest.

20535. Longwire Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-11 20:27:13 UTC
From: kj4fgi
Topic: 20535 Message: 20535

I would like some information on using 18 gauge coated wire for a Longwire Antenna. I have been experimenting with Wire Antennas and Baluns and Ununs. What I have behind my house is woods and than a cow pasture about a 1000 feet beyond the trees.

18 gauge wire is cheaper than 14/16 gauge wire and this is only an experiment so I don't want to spend much cash. I have used my Compound Bow to launch rope over trees (pull back ever so little) What I want to do is lay on the ground at least 300 feet of 18 gauge wire, use an Arrow with a 2 or 3 ounce sinker attached to the tip use the full 75 pound draw and let her rip.

I should get some distance out of it, sounds nuts, maybe, but I'm a Ham. I live under HOA rules and if they can't see the antenna from the street I will not have problems from the Board that's why I experiment with wire antennas.

Thanks Ed - KJ4FGI

Back calculation does not work
The mast itself has a windload that you can not make smaller
Say your rohn can hold up 10square meters (I know it is lower but just for easy calculating)
If it holds 10sqm in 70mph wind ... it can not hold 1sqm in 700mph (ok no wind is so strong) ...
I was just kidding a bit :-)

Windload is not a linear function and so not easy to calculate a load for a different speed
I know it can be calculated ... but that is not an easy task

See if a rohn is installed close to the ocean (were more wind is) ... maybe there the user has different numbers for this type op mast (but I am just guessing)
Dg9bfc
Sigi
Ps rohn should know that numbers ... so i would try again to ask them ... if not the manufacturer ... who else should have the safety margin numbers?!?

20537. Re: [ham-antennas] Longwire Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-11 20:47:06 UTC
From: ka9egw@britewerkz.com
Topic: 20535 Message: 20537

After 32 years as a ham and 10 before that as an SWL/BCL/MWDXer last year
I finally reached the end of my spool of #18AWG, stranded, tinned,
sky-blue pvc insulated wire.

Many, many experiments with random wires, dipoles for 160 and up, HF
loops, quads, wire arrays, and zepps came off that spool, along with a
couple spiral loops for LW and MW and a number of antenna coupler coils.
Plus some friends' antennas.

I lived many different places in my younger years, rentals, owns, HOA, no
HOA, zoning restrictions and the first few years in radio with a very
posessive [of his property in re: damage thereto] stepfather.

None of us ever had an issue with antenna visibility or robustness.

I'm thinking you're gonna need more than 300 feet to run out the full draw
of a 75-pounder...

20539. Re: [ham-antennas] Longwire Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-11 21:14:11 UTC
From: WA8JXM
Topic: 20535 Message: 20539

I've tried things like this in the past (more for height than distance) and the problem I always had was the wire getting tangled up either with itself or with the grass. 300' of wire is a lot to lay out and expect it to feed smoothly.

I used to have some 100' trees on a half acre lot.

Good luck.

I've used 18 gauge copper clad steel wire for a 80m loop for years. It's practically invisible from 30ft away and very strong of course, but not very flexible. It's not coated, gets brushed by trees and shrubs but has worked well.

The other 200 will be on the spool angled if it takes it off, 300 feet and the weight of the wire taken into consideration I don't think it would make the length of a football field, but I could be wrong.

I put up some wire like that years ago, but with a few differences. I taped a couple of fairly heavy bolts to the front of the arrow to give it a little more weight to pull with. Also just tied a string to the arrow, then used the string to pull up the wire.

They were all in and around W/NW/N outer metropolitan Chicago, ranging as far out as Waukegan, Fox Lake, Bloomingdale and Wauconda.

Keep in mind most of those years my world was pretty much limited to occasional ragchews on 160, occasional ragchews and regular traffic nets on 80 and 75, and traffic nets on 40...with only very occasional forays into the upper bands.

That being said, the best performer, without a doubt, was the 67' top-fed vertical worked against a 1/4 [electrical] wavelength tuned counterpoise from a 6th-floor balcony railing to a weight laid on the roof of my car parked about 20' out from the building.

All the rest were about equal--all being below 25 feet, excellent for close-in work on 160 and 80, and a couple hundred miles on 40. Most of them weren't even all that wonderful for that.

The 67' end-fed wire up about 15' regularly got to the west coast, Europe and South America on 15 and 10 during the late-70's/early-80's sunspot peak though...

The MW/BCB/160 spiral receiving loops all worked about the same; limiting factor being manmade QRN except in Bloomingdale where I was literally a couple hundred yards from a 50kW AM clear channel powerhouse.

Date: 2011-11-12 00:52:49 UTC
From: KA9EGW
Topic: 20535 Message: 20545

My most recent [current] antenna is a bent 135' off-center-fed dipole fed with 600 ohm open wire line. After numerous attempts over most of a week and a weekend involving a fishing rod and a 1 oz sinker, and most of a spool of 10-lb monofilament and a couple sinkers semi-permanent parts of my 12/12 pitch roof [can't walk it, or #14 house wire, across a shingled roof without it getting caught under the shingle tabs] I ended up using a 30' paint roller extension from the porch roof to place the wire.

Good luck with your archery experiments.

20546. Re: Advice on spacing - HF beam to 2m beam

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-12 01:26:06 UTC
From: ve9xyz
Topic: 20405 Message: 20546

Larry's comment on mounting the Cushcraft A148-10S vertically on a metallic mast has got me thinking... The manual shows this antenna mounted vertically on a pipe mount (about mid-span) and said nothing about this consideration.

Do others have some practical experience with mounting this antenna vertically with a metallic mast? I understand the potential for messing up the pattern as Larry says, but I was really hoping that Cushcraft had thought that through, and placed the mount in a spot that made it somewhat invisible to the beam.

For what it's worth my mount will have the mounting pipe continue past the A148-10S to support a 2 m ringo above it.

Maybe these are not such great ideas?

From: fred
Topic: 20535 Message: 20547

I was in an area where the HOA and CCR's were everywhere until I moved . The local gestapo were also not above looking over the fence into the back yard for violations . where I was no outside antennas allowed , period . I made my last dipole out of 1/16" galvanize lift cable , is strong , lightweight , flexible , corrosion resistant and most important almost invisible and inexpensive $.10/foot here . after it was up awhile it turned a dull grey colour and was very difficult to see against the sky , it was never spotted . you might want to use a flat nose arrow so that if it hits a tree it won't stick at 40 or 50 feet up . it worked well for many years and I still have it for use on field day .

Check with http://www.earchi.org. The end fed antenna uses a matchbox with 33ft dipole line.

My main antenna fed with UR-213 and LDG-Z11 check out http://hamwaves.com/cl-ocfd/history.html cannot fault it for getting out, better than my G5RV but be aware that in my case at least RF in shack and that is with ferites on coax, 1:1 balun in shack and ugly balan in shack, so have to use headphones otherwise I come out of radio speaker when transmitting but at least 2 S points higher in recieve than G5RV except on 15m where it is the same.

A true Windom antenna is not an "all band" antenna but rather a single wire fed antenna that works on even multiples of the fundamental frequency (e.g. 80/40/20/10 but not 60, 30, 15). Look in the ARRL Handbook or ARRL Antenna Manual.

OTOH, you can feed a random hunk of wire on about any frequency, but it's just a random wire then. Also a lot of people today feed an off center antenna with balanced wire and call that a Windom but that is more properly an OCF (Off Center Fed) dipole .

The other problem with a Windom is that, on receive, it tends to pick up more noise than a good dipole.

The typical half wave dipole is fed in the center with coax and can offer a reasonable match.

I suggest that you pick a good antenna book and study it and learn about antennas.

From: KA9EGW
Topic: 2400 Message: 20556

My current "Windom" ['current' as in 'at this time' I mean] consists of two pieces of wire, each of which forms one side of the antenna AND one side of the open-wire feeder. I used the end insulators, center insulator and line spreaders from the 73cnc dot com field day kit...no connection other than a satisfied customer. I figured out where to put the feedpoint by playing around in the ARRL-NEC program bundled with recent ARRL antenna books. My link-coupled tuner [refer to www dot cebik dot com] feeds it nicely except below about 3600kc I have to add some capacitance from one side to that end of the tank coil...the amount of capacitance needed is decreasing as the antenna continues to stretch and work-harden...about another foot and it ought to quit stretching if it's like the #18 I stretched with the Jeep...yeah, I know I should have pre-stretched this too, but I didn't really expect the first iteration to also be the final one...

Total fabrication time was about an hour. That's excluding many hours wasted losing fishing sinkers in trees, and trapping fishing line under shingle tabs, going to the store for another spool of [much heavier] fishing line, going back to the store for more sinkers, going back a 3rd time for mason's twine [f--- the fishline], going back a FOURTH time for more rope cause I forgot I gave some to the neighbor for one of his projects, then trip #5 to the mini-mart for ice and burn ointment [don't hold your hand right under the burning end of polyester rope when seizing the end with a zippo], and excluding putting up the gable-end brackets and masts [a story in itself] total erection...er, antenna-raising time was under a half hour.

If I had it to do over I would have simply put a mini zip tie around the rope and dipped the whole shebang in plastic pipe glue and left it to harden...after a 7th trip for pipe glue HI HI.

But if the supports already exist assembling the windom and it's open wire feedline ought to be a low-impact project.

20557. Coax question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-12 23:27:12 UTC
From: Steven Nelson
Topic: 104 Message: 20557

Ok...I know I am probably opening a can of worms...

I am installing a G5RV in my attic, and need to run some coax from the end point of the balun (it is fed with ladder line to a 4:1 balun), and need to connect that into my rig. I am running my old TS-530S, so I am not running a lot of power, nor am I expecting to pick up on the the weakest DX around.

My question is: is it really worth the extra money to buy the RG-8U, or can I simply get by with RG-58U? The 58U is easier to work with, but I know that the RG-8U has better transmission characteristics.

I would like to hear the groups thoughts on the price/performance between the two, or even if another coax spec would be better considered. I do have an MFJ-949 roller inductor tuner, so I can run different feed lines if necessary.

Any thoughts would be appreciated!

Thanks!

Steve

Another Ham and myself were discussing this very thing a couple of days ago regarding how to launch a wire over sturdy tree limbs up about 125 feet...

Instead of initially using the wire itself attached to the weighted aarow,, use a fishing casting reel with the small plastic test line that is on the real, launch your weighted aarow as planned with the crossbow or bow and let the line feed off of the reel set to freewheel in the casting ? position. there is minimal drag on the real and the fishing line, when you have the (weighted) aarow back down near the ground on the return trip remove the aarow from the line and attach your wire to the line, now reel back in the fishing line (line moving in reverse) and it will pull your wire back down to you..
Ok ?
Kim K7DGI and an old tymer who's name and call escape me..

From: roger.h@comcast.net
Topic: 104 Message: 20560

IMHO, RG 58 is only good for speaker wire. Very Very Lossy. In saving money mode, I went to Home Depot and bought several hundred feet of Dual sheild RG 6 cable tv coax. It's 75 ohm and works great for me on a 145' ZEP after balun. !65' to shack. I wouldn't run high power with it though. It was .24 cents per foot. It's not the best but good enough for me and it's mostly underground. It's got to be much better than RG 58. They have a higher quality RG 6 quad sheilded and it's much higher in cost. Google the specs on RG6 and see what you get. good luck Roger, 73, W4IV

http://www.lnrprecision.com/

The Co. above makes what your looking for but I just made my own which was a lot cheaper and seems to work fine; however, I'm just a starving RF engineer so I'm cheap.

Since it's a wire antenna you could stick in some PVC pipe or hang the top from a tree branch if you want true vertical mounting.

Mike

20563. RE: [ham-antennas] Coax question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-13 02:04:25 UTC
From: Richard Schmuke
Topic: 104 Message: 20563

Do some Google searches for coax loss. You will find that RG58U is OK for 80M but as you go higher in frequency the losses increase. Once you lose a signal be it incoming or outgoing you can't regain it. I would invest in the RG-8 size coax. This is just my outlook on coax. How short or long is your run of coax going to be ? My 450 ohm line runs to a switchable 1:1 or 4:1 balun then only about 18 inches of coax to the tuner. With a short run the RG58 is workable, I use RG-8X for some jumpers, 9913F for others and Belden 8237 outside

I am not familiar with your tuner, the only 949 I have worked with has a stepped coil not a roller inductor. I use a MFJ-962, MFJ-941 and homemade long wire tuner.

Rich , Kd0zz

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Coax question

Ok...I know I am probably opening a can of worms...

I am installing a G5RV in my attic, and need to run some coax from the end point of the balun (it is fed with ladder line to a 4:1 balun), and need to connect that into my rig. I am running my old TS-530S, so I am not running a lot of power, nor am I expecting to pick up on the the weakest DX around.

My question is: is it really worth the extra money to buy the RG-8U, or can I simply get by with RG-58U? The 58U is easier to work with, but I know that the RG-8U has better transmission characteristics.

I would like to hear the groups thoughts on the price/performance between the two, or even if another coax spec would be better considered. I do have an MFJ-949 roller inductor tuner, so I can run different feed lines if necessary.

Any thoughts would be appreciated!

Thanks!

From: Artekmedia
Topic: 20535 Message: 20564

I use an 8' surf rod with 40lb braided line and 2 to 3oz "bank sinker" .
I also tie a bit of fluorescent pink plastic (garden supply) tie to
make it easier to see the line on the other side . Once over the tree I
cut off the sinker and tie it to some 3/16" nylon line to pull back over
the tree. Never try to pull the sinker back up through the tree it
invariably wraps around a branch. Once I have the light rope up there I
can position it though the branches better by using an old fashioned
window sash weight (about 5 lbs) pull the weight up then let it fall
back closer to main trunk . I then put a pulley on the end of the rope
and pull that and the antenna hoisting line through the pulley. Once the
antenna is hooked to the line through the pulley I use the window sash
weight to hold the antenna taught while the tree sways in the wind .
This system will stay up a couple of years without wearing the rope
through. As a matter of course I change out the rope every couple of years

Steve

You don't say but I am guessing your coax run is less than 50' that plus the fact your running only about a 100 watts would say RG-58 will be fine ..if your really feeling unsure the RG-8X (smaller than RG-8) would be your next best bet. You will nopt experience enough loss in 50' of RG58 to talk about especially in an already compromised attic antenna situation

Good luck

Try RG8X. Better than RG58 and almost (90%) as good as RG8. RG8X is also just very slightly bigger than rg58

I guess 18 gauge is good enough, thank you for every ones help. I can not use any line and pull it over the tree, the trees are across a stream and it's like a forest so I will tie the wire to an arrow which is metal and weight it with a couple of bolts as suggested, but I will use a leader of non conducting rope.

Thanks to all for your help!!! Ed kj4fgi

OK Bran, stand corrected. Common mistake until you try to use the same adapter. RG8X is larger in diameter and uses the same one that RG6U 75 Ohm TV coax uses. Rad Shack has both.

20572. Re: Coax question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-13 12:18:04 UTC
From: Chris Baker
Topic: 104 Message: 20572

A true G5RV does not have a 4:1 balun @ the junction of the open wire & coax.

I would suggest you google the coax get the spec sheets & compare, for a short run RG 58 is ok but RG8 is better for longer runs.

If in the loft, why not make it into a doublet by replacing the feeder with a length of ribbon from the centre of the aerial to a 1:1 current balun at the AMU
(less loss in the ribbon cable & the 1:1 lets the AMU do the transforming work)

Thanks

Do you mean a true windom (single wire feeder) or the OCFD?
I run a simple 66' top OCFD fed 22' from one end to a 4:1 current balun to coax to the AMU.
Google OCFD or carolina windom

Thanks

Date: Sunday, November 13, 2011, 6:20 AM

Do you mean a true windom (single wire feeder) or the OCFD?
I run a simple 66' top OCFD fed 22' from one end to a 4:1 current balun to coax to the AMU.
Google OCFD or carolina windom

Thanks

20575. RE: [ham-antennas] Coax question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-13 13:13:48 UTC
From: KA9EGW
Topic: 104 Message: 20575

Now that this can of worms is opened...what sort of adapters go with LMR400? I'm pondering a better 2m antenna this winter, and the 17 feet of truckstop-CB-shop coax feeding my J-pole has GOT to go.

Anyone here ever had success making their own hardline for straight runs?

73, Brian KA9EGW

OK Bran, stand corrected. Common mistake until you try to use the same adapter. RG8X is larger in diameter and uses the same one that RG6U 75 Ohm TV coax uses. Rad Shack has both.

Good to know! I've even seen that mistake propagated on amateur radio retailer websites. Another long-standing "conventional wisdom" bites the dust... :-)

Originally that was the only kind there was. Weather is the first problem.
Wind the second.

Ok...I know I am probably opening a can of worms...

I am installing a G5RV in my attic, and need to run some coax from the end point of the balun (it is fed with ladder line to a 4:1 balun), and need to connect that into my rig. I am running my old TS-530S, so I am not running a lot of power, nor am I expecting to pick up on the the weakest DX around.

My question is: is it really worth the extra money to buy the RG-8U, or can I simply get by with RG-58U? The 58U is easier to work with, but I know that the RG-8U has better transmission characteristics.

I would like to hear the groups thoughts on the price/performance between the two, or even if another coax spec would be better considered. I do have an MFJ-949 roller inductor tuner, so I can run different feed lines if necessary.

Any thoughts would be appreciated!

Thanks!

Steve

The LMR400-UF (direct burial version) that I have has an inner conductor slightly larger than
regular RG-8/U, so special PL-259's and "N" connector are available for it.

Brian KA9EGW wrote:

> Anyone here ever had success making their own hardline for straight runs?

I've seen it in HAM magazines long ago, two sizes of copper tubing with insulators between. I think it is not practical, the tubing is not cheep and the insulation maternal hard to find and
work with, the store bought stuff takes advantages of modern manufacturing processes like laminating
copper foil over an aluminum rod and foam insulation covered with copper foil, the work and price
difference of making it your self a bad move, but you can use open wire feedline for straight runs
(at any frequency) a lot easier to make and lower loss.
Another alternative is to pick up scraps of 3/8", 1/2", and 3/4" aluminum cable system hard line.
Although it is 75 Ohms don't let that bother you. The only problem is you can't splice it without
buying splicing kits. (It can be done but the changes of a leak free joint is slim.)

20583. RE: [ham-antennas] Coax question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-13 20:12:03 UTC
From: Richard Schmuke
Topic: 104 Message: 20583

Please note LMR400-UF does not take special connectors. The center conductor is the same diameter as Belden 9913 and 9913F, it is a perfect fit for standard Amphenol PL-259. If you look at some of the cheaper knock off connectors the have a thicker wall on the center pin and will not work without reaming out to 7/64.

I get them here for as low as $1.65, Teflon ones are higher, $0.99 for the cheaper ones that don't fit the 400 or 9913.
http://www.gatewaycatalog.com/cgi-bin/category.cgi. I shop the local store and they carry several grades.

Rich

Subject: [ham-antennas] Vertical traps

Would anyone know a good website or websites showing how to construct traps for homebrew vertical antennas? I have Googled a number of sites but just can't find what I'm looking for.

Thanks.
Wayne

Ken,
Thanks for the info and I did bookmark that site. There are a lot of sites available but
just can't come up with one I really like.

The traps made with coax (and no capacitor) are superior to the old fashion kind with a separate
coil and capacitor.

Has anybody ever used a product called "Liquid Electrical Tape" for
sealing and weatherproofing connections? I saw some mention a few messages ago of using Plasti-Dip and it reminded me that I have a can
of "Electrical Tape" that I bought for something else and I've been thinking of using it on some connectors that'll be going up in the air in the next few days. It's similar to, if not the same as, PlastiDip.
Liquid vinyl I think. Anybody use this before?
Thanks in advance. Mike KC2RPX

From: Rene Wit de
Topic: 20549 Message: 20591

Hello everybody,
There is an interesting forum about no-tuner ,multiband end-feds 10-20-40M on a dutch site called "www.zendamateur.com"They have also made a copy of the 20M monoband end fed from PAR (now LNR http://www.lnrprecision.com/
http://www.zendamateur.com/viewtopic.php?f=5&t=6682&p=78102&hilit=end+fed#p78102
The site is entirely in Dutch, but there are many photos and schema`s you can use for your homebrew project.Try google translate to go from Dutch to US English.
Regards,
Rene, PD0RW

The typical half wave dipole is fed in the center with coax and can offer a reasonable match.

I suggest that you pick a good antenna book and study it and learn about antennas.

Ken

Topic: 20592 Message: 20592

Best antenna with NO 4:1 Balun would be:

Full wave LOOP on 160 with it being vertical....as much as possible....feed it in a corner (triangle or quad shape...doesnt matter) and worse SWR will be 3:1 at 2nd harmonic...use tuner and 1:1 balun.....

Have one of those at my rptr/remote base site......WORKS LIKE A HOSE!!!!

WHY 4:1??? A normal dipole uses 1:1...you COULD make a folded dipole that would need 4:1 but then you limit use on other bands....

Enjoy....

Chris

It should work well
But i would add a layer of plumbers tape on the connector before
plastidipping it or you have problems if you have to remove the cable later

I was showed by a old timer back sometime ago what a connector looks like after it has been sealed with tape for a couple of years. Pretty nasty. This elmer showed me a way to seal the end with out using tape and any kind of wrap and I been using it ever since with no fail so far. Just get some dielectric gel and fill the whole connector up with it. When you screw it up into the iso 239 it squeezes out everywhere making a water tight seal and keeps it nice and new looking. They use the same stuff to seal electrical parts on your vehicles the same way. It does tend to be a bit messy but works well. You can get it at your local auto parts store.

Sorry if this is a stupid question, but wouldn't a 2:1 balun be better? I thought a full wave loop had an impedance of around 100 ohms at resonance. Two to one would bring it to 50 ohms feed impedance.

Thanks.

Mike,

What's in the "matching network" the Web site refers to? A balun? An L/C network?

Thanks.

Frank, I agree with you, I have a 2:1 balun for a singleband loop and/or a wave and a half dipole, like doing 15 on a 40M antenna. You can make a coax transformer but the 2:1 balun is not limited to a single frequency. It is not a stupid question but a good idea, IMHO.

From: Artekmedia
Topic: 20549 Message: 20601

No significant difference whether fed at the top or the bottom when running in the vertical mode. Usually more practical to feed it at the bottom but If your hanging it out the 4th story window then of course feeding it a the "top" is more practical

20603. Re: Weatherproofing connections

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 15:14:20 UTC
From: pchapman920
Topic: 20589 Message: 20603

No experience with it but it is in the electrical department of a local Home Depot store.

20605. Re: [ham-antennas] Re: Weatherproofing connections

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 15:35:28 UTC
From: Joe
Topic: 20589 Message: 20605

The best weatherproofing I have ever come by was this.

Forget silicone the acid makes things worse.

What has never ever failed was this.

Use for this only a great quality electrical tape. not the cheap 1 buck
a roll but some expensive 3m Scotch brand one that has very rubbery
stretchy properties, where you can easily stretch it twice it's resting
length.

Make the connection. The wrap with a 50% overlap, wrap tightly the
connection area, Extending about a inch past the connection.
Then spray it with any outdoor type of spray paint. One that is made for
outdoor use UV stabilized etc.
When dry do another layer of the tape the same way, but go 1 inch
further past the end of the last taping. And again spray it with the paint.
And then do it again one more time tape again and extend an extra inch
again and spray down again.

Using this method I have even had connections underground in PVC that
was flooded with water so the connection is actually under water and
never have a problem at all.

20606. Re: [ham-antennas] Re: end fed antennas with coax half wave without tuner

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 15:37:23 UTC
From: Walt
Topic: 20549 Message: 20606

I may as well weigh in with my green ignorance. New ham with new setup. I purchased a OCF Dipole/Windom - 80-6 meters dipole.It comes with a 4:1 balun in the box at the connection point.
I have it mounted next to my house attached to two trees.
As it stands it is a gentle v shape, dropping from 22 feet to around 8 feet at each end of the run on both sides.
It contacts nothing as far as the trees, and is secured with flexible connections to allow for any movement
in the trees. My problem is the SWR is out of sight. I have a Yaesu 301-D with PS and Antenna Tuner. I set
up for which ever frequency and if I tune for any output, I get that much and more reflected power. I set up
for 10 meters, tune for say 25 watts and get that much in SWR or reflected power. Everything in the shack
is grounded, and I took the rig in to the local shop where it checked out perfectly, 120 watts out on several
bands on the dummy load. At the QTH, same story. My dumb questions, where do I start looking and for what.
I had an “ugly balan” in line which I removed in case of some problem I was unaware of.

Walt

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] end fed antennas with coax half wave without tuner

I would like to know is there a place to find a half wave antenna fed with coax without tuner and no counterpoise needed. I hope I can find one here on internet and photos thanks Robert

If your talking a slopping 1/2 wave antenna fed at the end, then
top or bottom feed makes no difference
Dave

20611. RE: [ham-antennas] Re: end fed antennas with coax half wave without tuner

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 16:45:41 UTC
From: Richard Schmuke
Topic: 20549 Message: 20611

Not being able to see just what you have things don't sound right. Don't worry about the gentle V , that is good enough to start, something is shorted out or a broken connection. A 4:1 balun cannot be checked with a ohm meter unless it is open because it will check as a dead short with a ohm meter. You can lower the OCD dipole and make sure you have continuity thru the antenna to the coax. You also need to remove the coax and check it for continuity pin to pin and shield to shield at the PL-259's and check that there is no continuity from the pin to the shield of the 259.

A "ugly balun" will cause no problem.

Do you have some coax so you can make a simple dipole for any band?

Rich, Kd0zz

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] On Behalf Of Walt
Sent: Monday, November 14, 2011 9:37 AM
To: ham-antennas@yahoogroups.com
Subject: Re: [ham-antennas] Re: end fed antennas with coax half wave without tuner

I may as well weigh in with my green ignorance. New ham with new setup. I purchased a OCF Dipole/Windom - 80-6 meters dipole.It comes with a 4:1 balun in the box at the connection point.
I have it mounted next to my house attached to two trees.
As it stands it is a gentle v shape, dropping from 22 feet to around 8 feet at each end of the run on both sides.
It contacts nothing as far as the trees, and is secured with flexible connections to allow for any movement
in the trees. My problem is the SWR is out of sight. I have a Yaesu 301-D with PS and Antenna Tuner. I set
up for which ever frequency and if I tune for any output, I get that much and more reflected power. I set up
for 10 meters, tune for say 25 watts and get that much in SWR or reflected power. Everything in the shack
is grounded, and I took the rig in to the local shop where it checked out perfectly, 120 watts out on several
bands on the dummy load. At the QTH, same story. My dumb questions, where do I start looking and for what.
I had an "ugly balan" in line which I removed in case of some problem I was unaware of.

Walt

20612. RE: [ham-antennas] Re: end fed antennas with coax half wave without tuner

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 16:57:23 UTC
From: Brian Williams
Topic: 20549 Message: 20612

Having the same problem with a G5RV I just put up and a R7 that I just took down. I have narrowed the list of suspects to Coax & barrel connectors which I plan to address next. Rig and all other assorted equipment work fine on 2 other antennas.

"Sometimes I think the surest sign that intelligent life exists elsewhere in the universe is that none of it has tried to contact us." Bill Watterson

Subject: RE: [ham-antennas] Re: end fed antennas with coax half wave without tuner

Not being able to see just what you have things don't sound right. Don't worry about the gentle V , that is good enough to start, something is shorted out or a broken connection. A 4:1 balun cannot be checked with a ohm meter unless it is open because it will check as a dead short with a ohm meter. You can lower the OCD dipole and make sure you have continuity thru the antenna to the coax. You also need to remove the coax and check it for continuity pin to pin and shield to shield at the PL-259's and check that there is no continuity from the pin to the shield of the 259.

A "ugly balun" will cause no problem.

Do you have some coax so you can make a simple dipole for any band?

Rich, Kd0zz

Subject: Re: [ham-antennas] Re: end fed antennas with coax half wave without tuner

I may as well weigh in with my green ignorance. New ham with new setup. I purchased a
OCF Dipole/Windom - 80-6 meters dipole.It comes with a 4:1 balun in the box at the connection point.
I have it mounted next to my house attached to two trees.
As it stands it is a gentle v shape, dropping from 22 feet to around 8 feet

at each end of the run on both sides.
It contacts nothing as far as the trees, and is secured with flexible connections to allow for any movement
in the trees. My problem is the SWR is out of sight. I have a Yaesu 301-D with PS and Antenna Tuner. I set
up for which ever frequency and if I tune for any output, I get that much and more reflected power. I set up
for 10 meters, tune for say 25 watts and get that much in SWR or reflected power. Everything in the shack
is grounded, and I took the rig in to the local shop where it checked out perfectly, 120 watts out on several
bands on the dummy load. At the QTH, same story. My dumb questions, where do I start looking and for what.
I had an "ugly balan" in line which I removed in case of some problem I was unaware of.

Walt

From: Larry Banks
Topic: 20549 Message: 20613

I know that this sounds simplistic -- but are you sure the SWR meter is connected in the right direction?

73 -- Larry -- W1DYJ

Oh and I think it is safe to say to really check this kind of problem with coax take the kind of analyzer that is out of the price range of most if not all hams. Best to swap out the coax.

"Sometimes I think the surest sign that intelligent life exists elsewhere in the universe is that none of it has tried to contact us." Bill Watterson

I am having problems with my direct tv satellite reception. When I transmit my reception goes away. Any ideas how to stop it? I have a low pass filter inline.
Thanks, Mike KI6SDO

20619. Re: [ham-antennas] RF noise with direct tv.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-14 18:26:29 UTC
From: Frank Kirschner
Topic: 20618 Message: 20619

It's almost certainly fundamental overload, not harmonics, that is, the energy at the fundamental frequency of your transmitter is getting into the satellite receiver and swamping the satellite signal. All the standard techniques apply: Move your ham antenna as far away from the satellite antenna, coax, and receivers as possible. Put high-pass filters on the coax at the satellite receiver(s). Put ferrite cores on the AC and other lines connected to the satellite receiver(s). Make sure your ham station is properly grounded. Reduce transmitter power. Other than that, it becomes a question of not watching TV and transmitting at the same time. Does your transmitter interfere with your neighbor's reception? (That probably isn't a good question to ask them.) Does it interfere with off-air reception? If so, it might be just the TV, not the satellite RX.

In spite of all the above precautions, my KW amp gets into the cable TV, computer speakers, and even my Select Comfort Sleep Number bed control. Reducing power to 200 watts helps, but there is still some interference with the cable TV, although it is still watchable.

Have the same thing with ATT-Uverse. My problem is that they use unshielded line.

I would guess you are getting into the phone line connected to the back of the receiver as that is the only thing, other than the box, that is not RF shielded.

Sounds like overload/desense. The farther you can move the Satellite dish from the ham antennas the better.

Does it only happen on some ham bands not others? If that is the case it may be that the coax feedline from the dish to the tuner is resonant at a particular ham band, changing the length of the satellite cable may solve the problem or "move it" to another band. Ferrite beads on the ends in the middle of the dish cable run may stop it

The impedance depends on height over ground
On fundamental frequency and on the lower bands (so low in wavelength over ground) the impedance can be way lower as 100 ohms!!

Subject: [ham-antennas] Weatherproofing connections

Has anybody ever used a product called "Liquid Electrical Tape" for
sealing and weatherproofing connections? I saw some mention a few messages ago of using Plasti-Dip and it reminded me that I have a can
of "Electrical Tape" that I bought for something else and I've been thinking of using it on some connectors that'll be going up in the air in the next few days. It's similar to, if not the same as, PlastiDip.
Liquid vinyl I think. Anybody use this before?
Thanks in advance. Mike KC2RPX

It almost certainly had nothing to do with anyone knowing your passwords.

All a spammer needs to do to send spam to ham-antennas, or any other group you're a member of, is to know your full email address and the fact that you're a member of this group. Easy to get that information from the computer of some other subscriber who receives individual emails.

Armed with that knowledge, the spammer can use his own SMTP server (or one he's stolen access to) to send emails to the group that say he is Chris Baker. He's not, but Yahoo groups does not use an even rudimentary method to determine whether an email has originated from a server authorized to send mail on your behalf.

Changing passwords doesn't solve the problem, and putting you on moderated status does nothing unless the spammer tries the same trick with your account again, which they almost never do.

Frank

Maybe this is a good issue to have a discussion with your local electrical inspector possibly they can raise the issue with the code people as in Canada the electrical manufactures are on the code rule committee.

Had a situation where a bad circuit design caused a fire and the manufacture was forced to modify the circuit design and make it more fail safe than the NEC/CSA people had approved. This issue went from the Fire Cheif's office who took possesion of the failed electrical device

Maybe the electrical inspector can force some design improvements to the FIOS power supply as its impacting the safety issue for the GFI device and the nuisance tripping. they likely have more clout than the average joe

What if senerio would be if home healh equipment eg home oxygen concentrator was on the same circuit and someones life was impacted by the nuisance trip.
.
I found when I was working the electronic compatibility is becomming a real issue these days as the electronics designs get made cheaper by the manufactures.

Hopefully they can go after the FIOS box designers.

Another possibility is to complain directly to the manufactures (TECHNICAL SUPPORT GROUP) of the FIOS box and let them know its tripping out the GFI circuit breakers manadaetd by the NEC code.

Amen! Larry. It is like putting your chain saw chain on wrong. It is so easy to do, you never think of it. You just notice it must need sharpened since it cuts to slow.

I know that this sounds simplistic -- but are you sure the SWR meter is connected in the right direction?

The best weatherproofing I have ever come by was this.

Forget silicone the acid makes things worse.

What has never ever failed was this.

Use for this only a great quality electrical tape. not the cheap 1 buck a roll but some expensive 3m Scotch brand one that has very rubbery stretchy properties, where you can easily stretch it twice it's resting length.

Make the connection. The wrap with a 50% overlap, wrap tightly the connection area, Extending about a inch past the connection.
Then spray it with any outdoor type of spray paint. One that is made for outdoor use UV stabilized etc.
When dry do another layer of the tape the same way, but go 1 inch further past the end of the last taping. And again spray it with the paint.
And then do it again one more time tape again and extend an extra inch again and spray down again.

Using this method I have even had connections underground in PVC that was flooded with water so the connection is actually under water and never have a problem at all.

Hi Wayne...

Making a trap for a wire antenna is pretty easy.... coil form, wire, capacitor, and mechanical connections to the form for the antenna wire.

Making traps for an aluminum tubing vertical is a totally different project. First you have to consider the main type of aluminum tubing; the next is to try and design a trap that will hold up to the vertical and bending stresses. A trap for a vertical antenna needs to be much more "robust" than for a wire antenna.

Look at a trap for the Hustler BTV series of verticals; heavy tubing swaged onto 1" diameter fiberglass. The fiberglass is used to separate the sections and as a coil form; the outside protective aluminum "cover" is adjustable and provides the capacitance for the trap.

There are other ways to do it, but none lend themselves to easy home construction.

The project, materials, and goals need to be defined further.

Coax traps are easy to make and you can use the coaxial trap calculator to make them. Wind them on a PVC pipe with end caps and run a fiberglass tube 1 inch diameter through the center. Attach the aluminum tubing to the fiberglass with 1 1/8 inch aluminum tubing.
Here is how to do it

From: James
Topic: 20584 Message: 20635

Hi Ron...

No, they are not. They are cheap to make, they are easy to make, they can be made with common materials available to hams; but, no, they are not better than a "normal" coil and cap traps. Losses are higher and the more common ones made from RG58 will deteriorate at high power.

Are they a piece of crap? No, you just have to know their limitations.
I'm in the process of adding 160m to an inverted "L"; with a coax trap for 80m, the length of the wire for 160 is about 25ft, but with a Reyco commercial trap, the length is 45ft. The Reyco is a convential L/C trap, and will handle the current legal limit without problems. It also provides less "loading" on the antenna and the 160m section gets to be longer and more efficient. Cost on the Reyco was about 30$US.

Coax traps can be made better by using optimum length-diameter ratios and moving the operations frequencies.

http://www.w8ji.com/traps.htm

http://www.qsl.net/on7eq/projects/coaxtraps.htm

http://www.seed-solutions.com/gregordy/Amateur%20Radio/Experimentation/CoaxTrap.htm

Above pages have been good references for me; the gregordy page cites the sommers reference for optimum L/C ratios.

Just a note... next year, I may try and use a coax trap in place of the commercial Reyco... if I try and add another band. The current length of wire gets me close to my property line; to shorten the "wiring" I would use the coax traps because of their increased loading effect on this antenna.

From: Frank Kirschner
Topic: 20531 Message: 20636

Sigi,

The wind load is generally considered to be inversely proportional to the square of the wind speed, so if the tower is good for 18 sq ft at 70 mph, it should be good for

18 * (70^2) / (90^2) = 10.88 sq ft

at 90 mph. However, this is a "back of the envelope" calculation, and a professional engineer might not take it as rigorous.

Rohn is the manufacturer, and I'm sure they know the figures. They won't release them, I suspect in part because they want to sell their more expensive (four times the cost) towers that are rated for 90 mph.

I had the same problem a while back too , the GFI that the frige and freezer were on would trip whenever I loaded up on 20 metres .the only way Iknew when it tripped was that the CO detector beeps whenever it loses power . was kind of impractible to install chokes and things and I tried a couple of different brands because I had them . there was no difference . I know this is against the NEC code but I live in a 70 year old house so should not have a problem with them , solution was to replace it with a standard outlet . not sure why it was there anyway , is not anywhere near water .

Good idea, but I asked them, and they sent me to Rohn. Rohn, in turn, sent me to Thomas Shelby & Co, who indicated they would provide signed and sealed drawings for $900, but didn't indicate that they would certify the design for 90 mph. If I get drawings for $900 certified for 85 mph, that does me no good, and costs about as much as the quad I intent to put up.

When "hackers" actually obtain someone's password, the first thing they do is change the password so the rightful owner can't change it and lock them out. The fact that in all of the cases we've seen here, the owners accessed their accounts after the incident with no problem indicates that the "hackers" did not, in fact, have the password. They were "spoofing" the email account, that is, sending out falsely identified emails made to look like they came from the legitimate sender.

All they need to do is subscribe to some groups, wait for emails, and spoof one of the many senders.

I own a domain name. There were, at one time, thousands of false emails being sent under that domain name a day, using email addresses for which there were no accounts at all, anywhere. If you have admin access to an SMTP server on the Internet, you can easily do this.

It only happens on 1 TV out of 3. The signal comes from the same splitter box.
Thanks for all the suggestions I will try them.

Then it's probably the TV itself, and not the satellite receiver. Try ferrite cores on all the cables attached to the TV (power, coax, audio, etc.)

Mike,
 I had this problem when I switched to Direct TV from Dish Network aabout a yeaar ago.
I had absolutely NO problems with Dish Network, but with Direct it was really doing wierd things like sometimes even turning the Direct Receiver off.
After checking things , using ferrite beads etc...I finally called Direct and they were very nice to work with.
They sent a guy out that had absolutely no idea about this stuff and didn't even know what "RF" was. Anyway, I had a number to call back and did so.I spoke to the same lady and told her that I needed a technician and not a contracted installer.
 The next day a guy was here and tried everything. Finally I asked him about the receiver itself. He said it was the latest and greatest. I asked if we could try another type. He had one on th etruck and sure enough all th eproblems went away.
 So you might just give them a call and explain what is going on. Maybe they can help you.
 Tom K5IID

By the way there is a forum on their website where some of the TVI problems have been discussed. I think I even wrote on it.

I have an HD DVR HR24-200 and when I key my IC7000 on CW or PSK or JT65 my DVR goes nuts. It changes channels, rolls screen, turn on or off record and eventually goes to a blue screen with a searching for signal and goes into a reset when transmitter is unkeyed. I have two DVR's and the bedroom is NOT HD and works fine. I suspect the front panel (touch screen like controls) is suspect to overload from a faulty design. I changed my remote to RF mode and that seemed to help. If you have an FCC label on the back of your remote you have an RF capable remote. I seem to have problems when I transmit above 30 watts or so. My next project is to see if enclosing the DVR in aluminum foil, thereby shielding it, will help. I don't think standard methods such as ferrite beads, grounding, etc will help a faulty design.

Try the beads first on the power cord and the cables ...you might be surprised ..a lot of RFI is "conducted" via the cabling. Also as a fun experiment try swapping the two DVR's and see if HR24-200 goes nuts when it is the bedroom.

Hi Dan...

Good to hear.. it looks to be a sturdy and weather resistant design.

I suppose a commercial LC trap could be adapted to a fiberglass support, but Gregg's design looks "better". Certainly, the diameter of the fiberglass could be changed to accommodate any associated tubing.

Well... now you've got me thinkin'.... I've got this bag of 10 army surplus fiberglass tent poles the came from ebay a couple of years ago...

Jim

Just as an added measure, I slid a piece of 6 inch diameter black shrink tubing over it to protect the coax and heat shrunk it. Been standing up well to the Florida heat and intense sun.
The sun keeps it shrunk HiHi.

Did that heat shrink tube lower fres? Did it lower q factor of the coil??
So that would add some loss I think

10 fibre-glass tent poles??? I have plans for a nice 80m vertical beam
antenna
Works as good as a 4-square but needs only one (non-metallic!) pole
No phasing-lines needed (cause parasitic elements are used) so easier to
feed

It is not easy to know if there is any loss of any kind .
It is a 1/4 wave vertical which has a wide bandpass by nature of it's length.
But, it loads just fine and works DX just fine.
Not sure why there would be any losses.

Best Regards
Dan Schaaf

This is common if there is no balun at the feed point.

> I tried a single snap-on ferrite core on the AC power cable of the FIOS

Sometimes GFI receptacle "false trip" troubles can be relieved by replacing the receptacle with a
standard receptacle and the standard breaker with a GFI breaker.

From: alphadeltacom
Topic: 20663 Message: 20664

We test the Model DX-CC at an apex height of 35 ft. as an inverted-V. Flat top configuration works well too. For longer distant DX performance higher is better but we have many reports of 100+ country DXCC results with the antenna at 35 ft. Depends on the band in use. 40-50 ft. works quite well.

Hi Sigi...

The fiberglass sectional poles have been available in the US for the last 10 or 15 years as military surplus. They were originally designed to hold up very large tents and come in a couple of different styles. Typically with a bag of 10, you can reach 40ft, but it needs to be guyed. A couple of web sites sell them, buy many are available on ebay in the US. The poles also available in high strength aluminum

Do a quick search on ebay... "mast", in the "Ham radio and CB" category and you'll see all the things that pop up. These things are over 40mm in diameter and quite strong. The shipping adds more to cost ... unless you can find a dealer at a swapfest.

Mine came in a carrying bag, and looked unused. Since US forces are withdrawing from desert areas, I expect the availability of these poles to dwindle over the next couple of years.

Hi All Being pretty skint but still wanting to do stuff I am considering getting a 3.9m fishing pole (ebay about £6.00 including del) and using self adhesive 1/4" copper tape helically wound on it so as to be a quarter wave for 20m, I was going to solder jumper wires across each section so it can be dismantled and having 4 quarter wavelength radials and put on stake for beach use. So has anybody done similar? What have I forgotten and should I just stick to brewing some beer instead? Jon G6UWK

Greetings all:

I have a refurbished Cushcraft R7000. I envision making a coax "pigtail" and connecting the R7000 thourgh my autotuner (ICOM AH4. In theory, the R7000 should not needs an antenna tuner, however, using an antenna analyser, I was able to get a close, but not acceptable match on 40m and 20m.

Will my proposed set-up overcome this SWR issue?

So has anybody done similar? What have I forgotten and should I just stick to brewing some beer instead? Jon G6UWK

Jon,

There are mobile antennas that are basically like that. There is no reason that you shouldn't experiment.

I don't know if 1/4" tape would give you enough room however. I would start out with wire first and adjust it until you approach the proper winding configuration.

Great idea! The helix will give you the lower bands with the fishing pole sticking out for good radiation. Use two to make a dipole.

Jon G6UWK

That would be a narrower bandwidth antenna than a fishing pole the correct length for a 20 meter
1/4 wl with a straight wire taped along it's length. (or copper foil)

From: Robert Costa, KB6QXM
Topic: 20675 Message: 20675

Hello,

My research is basically that the lower the dipole apex is below 1/2 wavelength, the higher the radiation angle. So the compromise is between local QSOs and working DX.

I have a vertical that I will use for DX until I eventually get my huge yagis in the air, until then it will be a dipole and a vertical. I had to drop the apex from 60 feet to about 40 feet to get it into the open. The.SWR matches the advertised SWR, except that 80 meters is only 25 khz versus the advertised 65 khz.

Does it work.....yes....is it optimum....don't know.

What is "close" ??? 1:2 or 1:3 or what ???
Your tuner will give the rig a good load but that does not say anything
about tranmitted power!!
The swr between tuner and antenna should be low or you will have additional
losses ...
If connection is SHORT (pigtail as you wrote) then your losses will be low
and everything is fine
Dg9bfc
Sigi
Years ago I used the fc1000 (almost the same thing as the ah4) in my car
with a military whip .... worked from topband to 10m!!

With modern rigs, they need a good match unless they have a tuner in them.

OTOH, sometimes we get too concerned about feedline losses due to SWR. I have successfully used a 20m inv vee (coax fed) on 30 and 40m. Or a 40m inverted vee on 30m. I don't even want to think about what the SWR is, but it does work. I even worked VK land with it.

If you are really concerned about feedline losses, use open wire :-)

(Ladder line is NOT open wire.)

No I'm not saying ignore the effect of feedline losses, but they are not the end of the world. Oh, BTW, most of my coax is 20-40 years old, some older. Yeah, I plan to replace it eventually.....

Whomever moderates this group. Can you let me know if some of my replies are going into your spam folder.

I have been told that if I reply to a thread my phone puts control characters into the subject line which in turn causes the mail to go into the spam folder.

I sent emails earlier today and did not see my emails in my inbox.

Look forward to the reply.

Does anyone use this as a traveling mast.. ? Do you have any info you can share on best practices since I just got one for $50 ?

Thanks

I am fairly new to this so take it with a grain of salt. A guy in my local ham club was telling me about an end-fed dipole that he inserted inside a very small diameter piece of pvc pipe that he ran up the trunk of a tree. I would imagine the same thing could be done with a flagpole.

We used a Gates fiberglass flagpole to hide a vertical a while back.
the radiator is silver soldered 1/2 copper pipe. It's held centered
with low expansion foam. The HOA allowed floodlights for a flag, so
that was used as the premise to run the conduit for the feedline and
power for the ATU.

The ATU and driven grounds are hidden in a water meter box at the base.
Link to an example:

Gloria,

I have a Flagpole made of PVC with a Trapped Hustler 6BTV inside .. see
link and attached

http://www.dxengineering.com/pdf/flagpole_antenna.pdf

Force 12 Flagpole Antenna

http://www.texasantennas.com/index.php?option=com_content&view=article&id=113&Itemid=62

Geoff Haines, N1GY had an article in QST where he used aluminum tube - like
a standard flagpole and just used a piece of PVC at the base as an
insulator (see attached pictures)

Some Articles on the legal side

Hi Sigi..

The link is to a company that buys and sells the military surplus masts. They might be able to do things others can't.

Does the US military still have any units based in Europe? If they do, give them a call and see if they sell off any of their surpluses, and when... you just never know. Might be sold out of a central location somewhere... you wouldn't think they would ship it back to the states... but it is the government, so you just never know!

20690. Re: Flagpole antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-19 20:29:58 UTC
From: James
Topic: 20685 Message: 20690

Hi Gloria...

The Hustler 6BTV is an ideal antenna for using inside a flagpole. If you can make the flagpole a little "fancier" and install "halyards" up to a crossbar at the top, then 12 and 17m can be added for the cost of some wire cored rope. Personally, I'm not a big fan of 12m, but I find 17m is a blast.

www.dxengineering.com/pdf/flagpole_antenna.pdf

http://www.dxengineering.com/Parts.asp?ID=3435&PLID=141&SecID=63&DeptID=22&PartNo=HUS-6BTV

http://www.sgcworld.com/20ftflagpoleinstall.html

www.oh1sa.net/data/antenna/Hustler/K7CIE_Hustler_doc.pdf

The last article shows that some installations require "extra effort".
I've also found that if the spoked hat above the 20m trap is removed, the 40m section can be lengthened an additional 30 inches or so, but that only effects the 4 and 5BTV... the 6BTV has a 30m trap and does not use the spoked hat.

The remote tuner installed at the pole base is also a good idea, but I don't think it will work any better than the trapped Hustler vertical.

Any vertical will only be as good as the radial system or ground screen beneath it, so you generally have to make some excuse as why your "maintaining" your lawn during installation. Most likely your available area is fairly small, but try and put in 18 or 24 radials at least as long as your antenna is high. If the area is bigger, go to 33ft for the radial length... that would be a quarter wavelength on 40m. Just an aside note.. all my radials are returned to the antenna mounting pipe via solder lugs and a large through bolt, three wires to a lug. Works fine, doesn't occupy much space.

On another note, my experience with the Hustler xBTV series is that they are built like tanks and will last a very long time. Mine was purchase used and already 20 years old when installed; new rain covers for the traps were purchased from Newtronics at reasonable cost. Because of their longevity, many can be purchased on the used market at reasonable cost. If purchased new, DX Engineering has decent prices and good service.

Good luck, and have some fun today....

Jim, K9JFK

From: Richard Schmuke
Topic: 20685 Message: 20691

Gloria, many of the antenna that have been noted have a capacitor hat, or little wires sticking out at the top. May I recommend a Mosley vertical, it is slim and no top wires.

http://www.mosley-electronics.com/pages/series/rv.htm

They are well made and I have had one a little over 30 years with no problem. They would fit in the PVC providing a good cover.

Rich, Kd0zz

20692. CR8900A Antenna Phase Coil Repir

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-20 06:58:34 UTC
From: SC
Topic: 20692 Message: 20692

Hi, I have a CR8900A and some Black Shrink Covering the Upper Phase Coils has some small tears and you can just barely see the coils. I was thinking of using some Butyl and Electrical tape that I have form TESSCO I have good SWR's and don't want to Wreck them with the repair any help would be greatly appreciated

Thanks

Shon KJ6FNN

20693. 1000 foot loop antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-20 08:23:38 UTC
From: s3hampton
Topic: 20693 Message: 20693

Good day; This is my first posting to this group.

I just finished erecting a new loop antenna. It is about 1000 feet long, and is averaging 35 feet above the ground. It is in an open field, and is at least 60 feet from any trees on one side.

I have two other loop antennas, both being 1 WL on 160 meters. Both of these 1 WL loop antennas are fed with shorter lengths (50 and 80 feet?) of 450 Ohm window line, via a high quality 4:1 current balun. These other loops work well on all bands.

On 75 meters, the old (1 WL) loops seem to work better than the new 1000 foot loop, MOST OF THE TIME. (ON the higher bands, the new 1000 foot loop has a distinct advantage, MOST OF THE TIME.

I am genuinely surprised that the new loop is not working as well (in some cases) than the old 1 WL loops!

Here are some points of interest:

New loop is about 1000 feet long.
The loop is made with #14 stranded THHN wire.
The loop antenna is five-sided.
The antenna uses a 50', a 40', and three 38' masts.
All five masts are in an OPEN FIELD.
The feed-line is now 300 Ohm window-line.
The feed-line is now 220 feet long.
The feed-line is fed by a high-quality 4:1 current balun.
The balun is fed by about 15' of RG-8 coax.

SWR vs. Frequency measurements
(SWR = n-to-one; Tuner BYPASSED.)
(Measured during a SLIGHTLY damp (light snow) period 11-19-2011.)

FREQUENCY ORIGINAL NEW 1000'
(MHZ) N. LOOP N. LOOP
1.85 5.2 1.0
3.75 1.7 1.0
3.86 1.8 2.2
3.99 2.4 3.3
14.30 1.2 1.0
14.33 1.3 1.0
18.30 1.0 1.3
21.30 1.0 2.0
24.95 3.2 2.8
28.4 1.3 1.8

I had previously fed the loop antenna with 150 feet of 300 Ohm window-line to an AH-4 ATU, which was fed with coax to make up the feed-line between the AH-4 and the radio.

I now have the proper length of 300 Ohm window line in place; The AH-4 (and RG-8) is no longer in service.

I sense no difference between the two methods of feeding the antenna. (Using a shorter run of 300 Ohm window line with the AH-4 and coax, vs. the full run of 300 Ohm line between the balun and the antenna's feed point.

THE QUESTIONS:
I now have 250 feet of 450 window line on order; It is made from #14 stranded wire.
- Will this 450 Ohm LINE work better than the 300 Ohm line?
- I need 220 feet between the balun and the feed point of the antenna: Were the 150 and 220 foot lengths of 300 Ohm line INCORRECT?
- What length of 450 Ohm line will be the best?

I mainly operate on 75, 20 and 17 meters. (3.9, 14.3 and 18.4 Mhz.) - What are the considerations?
- Will the LENGTH of the feed line make a difference?
- Will the use of 450 vs. 300 Ohm window line make a difference?

Thank you!!!
73; -Mike- KØJTA

Normal thing ... a 1wl loop fires straight up
Make a 2wl (or 4 wk) loop and you have a "hole" upwards
Good for dx but bad for short skip (nvis)

NO!
> - I need 220 feet between the balun and the feed point of the antenna:
> Were the 150 and 220 foot lengths of 300 Ohm line INCORRECT?

>>>>> On every different band you have different impedance at the
feeding-point ... and that is transformed with the feeding-line to a
different value at the other end ... so you have to make some tests, make
notes of that, change length of feeding-line, make another test on all bands
... ...
After first test you see if one of your bands has high swr (and the other
bands swr is low) ... then add (or shorten) the feedingline ...
And note the changes on all bands ... and so on ... till you find your
"sweet spot" :-)

> - What length of 450 Ohm line will be the best?

>>>> That length that gives you lowest swr on your favourite bands
On my loop I made the loop a bit bigger and the feedingline a bit shorter
(as I had it on first setup)
That didn□t change much on the lower bands but that helped to get the swr
down on 17 and 30m (may be different on your big loop)
For a real multiband setup it is a lot of cutntry
But it is worth doing it (every decibel counts at the end)

>
> I mainly operate on 75, 20 and 17 meters. (3.9, 14.3 and 18.4 Mhz.) - What
> are the considerations?
> - Will the LENGTH of the feed line make a difference?

Not on performance of the loop itself but on feeding-point swr and balun
losses

>>>> Balanced line has such a low loss that you will never notice any
difference if using 300 ohms or 450 ohms or window line or real ladderline
(with open spreaders)
> - Will the use of 450 vs. 300 Ohm window line make a difference?

Mike (K0JTA),

A question and a few comments from me. What do you mean by the smaller loop "working better" on the lower bands? Is your situation about high SWR or signal strength?

I experimented with large random length loops years ago and found several things. 1) lengthening or shorting the length of balanced line and/or coax by trial and error can sometimes greatly help reduce high SWR. 2) Keep your 300/450 ohm line off the ground and away from metal objects! Proximity to such will usually introduce a very high impedance spike that makes balanced line quite lossy. 3) you may need to lengthen or shorten your loop to find a "sweet spot" that gives you reasonably low SWR at your tuner or rig. 4) the loop that got out the best for me was approximately 750' long, thrown over branches 30-45' off the ground in the woods. I could never get the SWR on a few bands lower than 4:1 but the antenna got out like gangbusters. On 160 and 80, I'm guessing it was good only for 500 miles but signal reports were strong with my 200W. On 40 and higher, it became much more effective for longer distances, although I felt that on 12 and 10 there were so many lobes coming off the loop that its directivity was unpredictable.

Consequently, I feel that your loop's performance should be not unlike what I experienced. There are times when an S-meter is a better judge of an antenna's performance than an SWR meter. Keep tinkering!

Hope this helps,

20698. Re-visiting the G5RV

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-20 18:59:45 UTC
From: rrath
Topic: 20698 Message: 20698

I posted here a little while ago about an NVIS antenna mounted on a metal roof. I was shot down. I was told it is too long and the city department head does not like wire antennas. So I asked the city to buy a very expensive hf beam, know they would laugh and say no. I was told to look at something smaller in size. Thus the G5RV came into play.

Here is my question:

The G5RV incorporate ladder line approx 33.7' long. Now we will be mounting it at 10' above the metal roof. I do not know antenna design very much, but I would think we will have issues with the ladder line being in close proximity with the metal roof. Can we remove the ladder line and insert a balun, unan or something in place of the ladder line?

We (city EOC) will be running an Icom 706mkllg with the Icom 180 auto tuner and about 85 watts.

I can see some of you shaking your head and laughing - what is this guy thinking?? Answer: the city wants something for nothing. If it was up to me, I would put up a 1000' loop and call it good. But I have to work with the city. They do not understand tx type antennas. I have tried to explain it and they have tunnel vision about using a small pc of wire and picking up stations all around the world. That is rx and not tx - big difference.

Any help - ideas - would be great.

Thank you.
Rod

Rod,

As long as the ladder line is balanced to the metal roof and not too close (e.g. 10x the width of the ladder line) it will be okay AS LONG AS IT DOESN'T MOVE AROUND IN THE WIND. Realize that the ladder line in a G5RV is part of the radiator. If it moves around a lot in relation to a large metal object, it will affect the tuning and the radiation.

Why not just put a remote tuner near the antenna feed point and a short piece of ladder line to the tuner and run a simple dipole of whatever length fits in? That way you can put the antenna where ever you can fit it. Of course, 100' or 150' would be good for 75 m and the bands above it but other lengths will work too.

A G5RV ideally depends on being up in the clear with the feedline likewise in the clear. A simple dipole with a tuner is much more adaptable.

From: Chuck
Topic: 20700 Message: 20700

What I need help with, I need a oscillator tunable from 1 to 3 Ghz with at least 10mw output hopefully 20mw for a project I am working on. Even a design will help.

I have priced some Rf generators that can do it but they cost about 10 grand and more, If one of you have rf gen. that can do this and live in range of Vermont that too would help...

Thanks Much...

I would put up a 40 M dipole about 10’ off the roof. Put an “UGLY BALUN” at the top of the coax feedline. Get the wire from the city. If it doesn’t work the G5RV isn’t likely going to work either and you saved some money.

73, WY6L

Remember the engineers said a bumblebee couldn't fly and guess what, it did.

I think you also should re-visit your choice of balum. I am thinking maybe 12:1 or at the least 9:1.

I have a wire up 75 feet feed with a 600 ohm ladder thru a 12:1 and have no trouble hearing or talking to anyone.
As far as testing that is about all you can do anyway.

Very interesting!!!

I am now using a high quality 4:1 current balun; Is this the best choice for RF energy transfer?

- Might I be better advised to use a 1:1 with 450 Ohm line?
- Might I be better advised to use a 4:1 with 450 Ohm line?
- Might I be better advised to use a 1:1 with 300 Ohm line?
- Might I be better advised to use a 4:1 with 300 Ohm line?

OK!! This seems to be logical. (And, it is an easy thing for me to understand and follow. THANK YOU!!)

Again, this makes perfect sense. (Thanks.)

>
> > - Will the LENGTH of the feed line make a difference?
>
> Not on performance of the loop itself but on feeding-point swr and balun

This brings up my earlier question of what would my "best choice" again:

- Use a 1:1 or 4:1 balun?

- Use 300 or 450 Ohm window line?

>
> >>>> Balanced line has such a low loss that you will never notice any

> (with open spreaders)
> > - Will the use of 450 vs. 300 Ohm window line make a difference?
> >>>> see above ... only measureable differences
> Greetz Dg9bfc Sigi
>

OK; No real difference between 300 or 450 Ohm window line as the feeder. (I am assuming that the comparison of 300 and 450 Ohm line would be that each would have the same wire size...

My point: The 300 Ohm line that I now have is made with #18 wire. The 450 Ohm line is made with #14 wire. (Heavier wire is BETTER?)

- Also, is there a logic for the Balun design choice of either 1:1 or 4:1? (I am thinking that there is a "better choice" between the two; Perhaps this is another choice/factor that would offer little real-world difference?)

Thank you VERY MUCH for your time and effort, Sigi!!

I have found that the larger loop offers poorer signals, both receive and transmit on 75 meters.

This is easily referenced by my ability to quickly select (1) the 1000 foot loop, (2) a 540 foot loop, or (3) a 80/40 meter dipole.

On 75 meters, the 1000 foot loop is 10 dB weaker (RX and TX modes) as compared to the 540 foot loop. (The dipole is almost always STRONGER than the 1000 foot loop, but somewhat weaker than the 540 foot loop.)

On 20 meters and higher, I believe the longer loop has the edge over either of the other two reference antennas.

In all cases, I am using a tuner; The tuner's output is routed to the 4:1 Balun via 15 feet of RG-8 coax. The 4:1 Balun feeds the 300 Ohm window line.

The feed line is LONG, as it is 220 feet!

The fact that the 1000 foot loop is (most often) 10 dB WEAKER than the dipole or the 540 foot loop is curious! (And, disappointing!) And this is why I am considering changing from 300 Ohm (#18 wire) to 450 Ohm (#14 wire as the feed line!

I now am using the same high-quality 4:1 Balun on BOTH loop antennas. (Might I be better advised to get a 1:1 Balun?)

Absolutely a great help, Bob!! -And, yes: I do not put too much importance on the SWR indications. (The auto-tuner covers the sins of any SWR...) The S-meter HERE and at the OTHER PERSON'S STATION are the things that I place the most importance on!

I found it interesting that you had arrived at a 750 foot loop length! How did this come about? (Did you keep shortening the loop until "it worked best" on which bands?)

I am curious: Do you have the ability to select another antenna, and use this as a reference? In my case, I can select the 1000 foot loop, a 540 foot loop and a 40/80 meter dipole... The 1000 foot loop is about 10 dB weaker (RX and TX) as compared to the 540 foot loop on 75 meters.

The bigger window line has lower loss ... so far so good . but only measurable difference to the 300 ohms line

The 1:4 will work better (regardless what feeding-line you use)

Reason: on fundamental the loop has a lower impedance BUT your loop is big ... so even on lowest band it is used on a harmonic ... so impedance will go up to "a few hundred ohms" ... so the line is matched (almost) and does not transform much from loop to balun
And so your impedance down at the balun also will be a few hundred ohms
Easy to match that with a 1:4
...
If you can you should use a resonant length of ladderline (halfwave for topband) or fullwave for 80

That will make absolutely no transforming and you have the same impedance (more or less) at the balun and at the loop

Make BOTH (loop and feeding) a bit to long and make notes
Cut and try
Make another testrun etc. ... ...

I did that with my loop and no i need NO tuner on most bands ... and on the other bands it is always lower as 1:3 (o internal tuner can match the load and losses are low)
Ok I needed a few days for doing this
And for easy remembering what I did and what did change I made an excelsheet for my notes

Dg9bfc
Sigi

Ps big loops are lousy for short skip ... but for long distance they are very good

Lots of used HP gear on Evil bay that will cover this frequency range
for $500 or less ..even more form $500 to $1000

Now if your budget is $100 that's another story...maybe something like a
hp 3205A or hp 8616a ?

Hi Rod,

I would suggest some thing a little more basic. Point out to the city that they are relying on you for fear of there com system going down. Sense they have to rely on you this proves they have no faith in the technology of their system. Perhaps they should listen and let you do things correctly. Now while this statement is brief, I am sure you understand where I am going with it.

Good Luck!

Not sure if you mentioned what frequencies you plan to use, but perhaps a trap dipole might be "small" enough to be acceptable and allow you to go with all coax to the radio,saving you having to "mess" with ladder line.

Have you tried finding out what other EMCOMM stations in your area have done ? Maybe strike up a question at the next state meeting ... Learning from other peoples trials is always cheaper !
anyway - take a look at this link .
http://www.starc.org/technotes/75-40%20meter-nvis.html and on a dipole - the higher the antenna the lower the launch angle is (better for DX) the lower the antenna the higher the launch angle is (better for NVIS) . hope this helps

To compute the FULL WAVE FOR 80 resonant length of twin-lead feeder:

- Compute this with the traditional formula? (468 / freq in mhz)

- Compute this with same formula, TIMES THE SHIFTED VELOCITY FACTOR of plastic covered feed line?

- Is this information the same for both 300 and 450 Ohm window line?

>
> That will make absolutely no transforming and you have the same impedance
> (more or less) at the balun and at the loop
>

My existing 300 Ohm feed line is 220 feet.

- What is a good "target" length to choose?

- With some effort, I could modify the route of the feed line, to make it LONGER.

- It would be impossible to make the feed lime any shorter, though.

Thank you!!!!!

Resonant lenght is WITH velocity factor
Windowline is different then open wire (open line close to 1, window line is 0.9)
With your 220 feet you are close :-)
67m is a bit short
80m*0.9=72m
But maybe if your loop is a bit long it is exact what you need
You have to make a table (like I did in excel) and after every change make a note ...
Exact measurement is not needed ... it is a cutntry setup

You can make the loop a bit shorter and the feeding-line a bit longer (or other way around)

At the lower end (the balun) the result will be nearly the same on the lower bands BUT it will influence the resonant points on the higher bands!!!

The thing is that THE WHOLE system has to be resonant and that on all bands the swr is low ... and that is a bit of work

All antennas are influenced by ground, shape, height ...etc etc so I can not say what you need ...

If you sweep your antenna system with an analyzer (or trx with lowest power setting and damping between output and antenna (to safe the trx if high swr)
You will find many many points where the swr is low

Every few hundred kc the impedance will go up and down and you have to bring the low swr points in the bands of interest

Swr 1:1 is not needed (but good to have)

The goal is low swr to keep losses low

And with cut and try and making notes it is a lot of work ... but IT IS WORTH DOING IT!!

I have a question.

I've been following this thread off and on, and am wondering if a balanced output tuner directly feeding the window line wouldn't be a better way to go? Not one of the tuners with a balun after the matching network, but one with the balun at the input side.
Would the seeming need for resonance then fall out of the equation?
Recognizing that the feeder length would still be somewhat critical to keep the load within the range of the matching network.

Stan

Subject: [moderatorcentral] emails being rejected for "policy
reasons" and applications back online

A couple of updates we wanted folks to be aware of:

First, we have made some change recently to block the ability of
spammers to post to groups by "spoofing" the email addresses of real
group members.

However, a side effect of these changes is that some legitimate
messages could be blocked, particularly if a user is posting via an
"external email client" that does not have its SMTP configuration set
to correctly identify the source of the message.

You will know if your messages are being affected by this problem if
you receive a bounce message letting you know that your email has
been rejected for "policy reasons" or "community guidelines violations".

You can learn more about this issue, and how to correctly configure
your SMTP settings, here:
<http://help.yahoo.com/l/us/yahoo/groups/original/members/troubleshooting/ygcuflow-35.html
>http://help.yahoo.com/l/us/yahoo/groups/original/members/troubleshooting/ygcuflow-35.html

Meanwhile, our apologies for any inconvenience this change has
caused. But the good news is that the fix has enabled us to block
tens of millions of messages from spammers that otherwise may have
successfully posted to groups.

2. Belated notice that the problem with Applications described here
has been resolved:
<http://groups.yahoo.com/group/moderatorcentral/message/178>http://groups.yahoo.com/group/
moderatorcentral/message/178

Thank you,

Subject: [OKtraders] radio shop sell out by: kc5dbh
X-Yahoo-Newman-Property: groups-email-ff-m
Content-Type: multipart/alternative;
boundary="5DAx3GL2Imwq1r68Pkv2gPsDbYcxo7BxQruSjY3"

Folks,

During the month of December and possibly the first week of January,
I will be cleaning out a two-way radio shop. Much of the stuff is
obsolete for commercial use but may be useful for amateur use. I do
not know for sure what is there and what is not. I expect to find at
least a couple of working Cushman service monitors, some radio
programming equipment (some with software, some without), GE,
Motorola and, Midland radio parts. I suspect I will encounter a
quantity of Midland service parts along with some Maxon and, Icom
service parts. I do not anticipate any real amount of Motorola,
GE/Ericsson/MaCom/Harris, Kenwood or, Vertex Standard/Yaesu parts
except a few parts incidental to a previous repair job(s).

There is likely to be some other test equipments including a couple
of vintage Motorola and GE test sets along with a couple of
wattmeters and standalone radio programmers.

I also anticipate a quantity of used parts for GE Mastr II and
Motorola Micor/Mitrek series radios although most of it will be
either for base radios or will be crystal elements.

I also anticipate locating some vintage service manuals including
Motorola, RCA and, GE manuals. If there are any manuals you are
looking for, please e-mail me at
<mailto:kc5dbh%40yahoo.com>kc5dbh@... (no spammers, you will be
blocked permanently) and I'll keep an eye out while I'm going through
the stuff.

Once I go through the facility, I'll create a list of functional,
repairable and, saleable equipment. When I get the list together;
I'll post it here on the group page.

73's de

KC5DBH Matt

From: Siegfried Jackstien
Topic: 20693 Message: 20717

Sure is a real balanced tuner better ... but if you carefully cut the loop
AND feedingline that you have low swr on all or most bands then it can work
as good with an unbalanced tuner and remote balun
The thing is to keep the balun happy (low loss) and to keep the swr low in
the SHORT coax run from balun to tuner (if balun is remote/outside)

If balun is INSIDE tuner (on output) it is the same thing
Keep swr low with tuner in bridged mode (only balun in action)
That will keep the balun losses low and the tuner has an easy job when
switched in

And if you have a real balanced tuner with balun on input side ... also then
you can improve the system if you carefully search for the right length of
ladderline and loop ...
A balanced tuner has normally a wide tuning range but it is possible that on
some bands you do not find a good match (or find one that is tricky to tune)
Changing the length of the feeding-line can help in this situation

So ... yes you are right ... a balanced tuner might be better in some
situation ... but some hams can not bring ladder-line in the shack (or do
not want to do this cause fear of rfi) ... and for that you can mount a
balun remote and have almost the same performance (if length of antenna and
feeding-line is well chosen)

What bands are you listening to ???
They seem to be quite full.
Especially 10 and 12 meters

It doesn't seem that way to me. I heard more stations on 10 meters in the last month than I did in the previous 49 years. Any station that doesn't begin with a W or K (and even some that do) engenders a pile-up. There is exotic DX on every band.

Some of it may be that I finally have a decent antenna. I spent many years in the military, and lugged around a Cushcraft R7, or hid a dipole in the attic of a rented house. Now I have a 102-ft doublet at about 70 feet, and DX is great.

But it seems to me that there is more activity. Sun spots help, but in the last ARRL SS, there were loads of US stations on. Maybe that's just me.

Right
I got back on the air in Aug 2005 and I have 317 countries worked and confirmed and 9 Band DXCC credits and WAS and WAZ since 2005.
Almost 100 countries on 6 meters.
The bands have been alive and well and hopping since Sept on 12 and 10 meters due to the Solar Flux Index being high.

Back in my early days (1963), almost every evening, 80 meter cw would be wall to wall occupied (all 300 kHz of the CW subband). I mean every kHz was occupied. Some evenings it could take you five minutes to find an unoccupied spot to call CQ. The phone portion was even worse. Likewise 40m and 20m.

Now you can tune 25-50 kHz and not hear a single signal.

Similarly 2m after the advent of repeaters (1970). Morning and evening drive time had at least a half dozen or more repeaters in steady operation (Cincinnati area). Now I can listen and rarely hear any use even during drive time. I was talking with a ham in Colorado who has a mountain top repeater that no one has used in months.

You say 10m is "full"????? I can still tune 25 or 50 kHz portions and not hear anything even in the popular segments although the band is very much open since I hear plenty of signals on the PSK frequency. I just tuned 28.6 to 29.1, a half megahertz, and didn't hear a single signal. The band certainly is not "full", at least according to my definition.

The only time I hear the bands "full" is on a weekend with a major contest. It used to be that way even without a contest.

Ken I agree with you 100% in everything you say below.

In the 70's you for the most part had to answer a CQ because there was no empty spots on the bands period. no matter how tight of a filter you had .25Kc was still too wide.

You even with a filter that wide operated with most times at least a second sqo going on and sometime even two can be heard, this was normal every day operating.

I agree with Ken

Due to 2 sequential moves and less than ideal antenna locations and the energy required to start my own business I had not been on the HF bands up until 3-weeks ago for the first time in 9 years. When I first started tuning the bands 3 weeks ago things were so dead (relative to even 10 years ago) that at first I thought damn I get on for the first time in 9 years and we are having a solar storm. Turns out no solar storm at all just that many less people on . Worked some amazing DX barefoot through modest pileups, barefoot with a butternut vertical so conditions were good ...just no competition for the DX.

As ken said 80, 75 and 20 used to be wall to wall 24/7, 40 was never a hot band in those days because of all the foreign broadcast on the band which is now 99% gone. 10 meters seems busy now because of the solar cycle but no more than in cycles past..good place to work the world with modest antennas and equipment which is why it is popular now.

Now gotta go put a few more wires before CQWW :-)

Yes, Dave. The other thing I've noticed is that DX is CALLING ME! That was something that never happened in the old days when W/K calls dominated the bands.

Yes, it's easier for U.S. hams to work DX because W/K stations are no where as common as they used to be.

I was first licensed in late 1957, during the famous Cycle 19 -- I agree with comments about the massive amount of signals, even on the Novice sub-bands. I'm guessing that much of the present population of new hams is starting on VHF/UHF -- which leaves more room for me to work DX with my meager 100 watts & wires! Nice to see the numbers going up, however.

They must be hiding on 1200 MHz or something because I certainly don't here them or 2m or 440.

I actually packed the 6/2/440 FM rig away because there is no activity. Okay, I'm rural, but I can hear the repeaters even in the bigger cities and there is little activity.

I have to suspect that many of the newly licensed hams never get beyond a 2m hand held, if they even get that far. And then they give up. Don't forget, today's numbers are inflated by the 10 year renewal cycle. It used to be five years AND you had to certify that you were active to renew.

Many folks are recruited into the hobby, just to find that they either cannot afford to gear up or find that there are more immediate pleasures satisfied through gaming, texting etc. at a lower cost.
And, in today's digital world, many of those recruits choose digital modes such as PSK.

It does appear that most clubs who bring new people into the hobby (at least in the US) are indeed the FM repeater type of clubs. Most of them become involved with public service, and rarely are exposed to the various other aspects of this hobby, including antennas.

But it's not good for the hobby if old timers (I include myself - licensed for almost 35 years), continue the mantra of how things were different many years ago. That only serves to alienate people, and causes harm to all of us.

Sorry, Sebastian, I don't see that we are alienating anyone. I do think it is a legitimate concern that although our licensed numbers are almost 3x what they used to be, actual on the air activity is down. IMO, the licensed numbers hide the actual decline of the hobby.

Now if someone wants to convince me that we really have more people active, be it experimenting on short distance 1200 and 2300 MHz work, or in other activities that I don't see, that would be great.

*To add a different note to this discussion, I'm newly-licensed at the Tech grade as KF7SIS. The next exam session I'll go for General. I've wanted to get into amateur radio since I was 9. I'm 54 now. It was about time.

I have two principal interests so far: active involvement in ARES/RACES on 2 meter and higher; and HF (40m to start with) for CW, DX, and QRP. In order to do anything other than listen on 40 I need to get my code up to speed--I figure at least 10wpm with a straight key. I might try paddle keyers sometime, but I'm a traditionalist.

Along that same line, for everything under 2 meters I will home brew my gear and antennas. I used to make my living in electronics engineering, so I have some skills. But I'll leave the VHF/UHF stuff to factory-made gear. For my involvement in ARES/RACES I need gear that's up to date, dual-band, programmable, PL-ready, etc.

I've become involved in the local Ham club, and after the first of the year I'll be involved with the local ARES folks. I've already begun the online training courses.

I like avocations (sorry, I don't like the word "hobby" as some people use it to trivialize things people do other than earn money) that combine my interests with public interests, and amateur radio has certainly proved its ability to serve the public.

Best regards,

Todd

You know, there are experimenters that have a license to test their projects on the air. There are QRPers who focus on one frequency. There are hikers and mountain climbers who get on the air and there are those who are happy to make 1 QSO or 2 per day. Most of these guys are not obliterating the airwaves.
Then there are the VHF guys who are not HFers and the VHF bands are not hopping 24/7 due to limited propagation.

The gear is cheaper today (in actual dollars) or in hours worked than it was 40 years ago. Early 2m handhelds and mobiles were in the $300 range. A pair of Drake Twins (receiver, transmitter and power supply) were about $1000. In those days, that was significant money in terms of hours worked to buy one. The top of the line (Collins S-line) was around $3500 IIRC.

In the 1969 Handbook, Swan HF transceivers were advertised for $420 to $520. That's roughly equivalent to $4000+ now, and they were middle of the line. Gas was under 40 cents per gallon then. Oh yeah, the ARRL Handbook was $4 (compared to $50 now) and the ARRL Antenna Book was $2.

OTOH, my first transmitter was built out of salvaged TV parts and a few parts bought new or surplus.

I agree, however, a lot of the excitement can be found in other venues today.

The CW on 80 meters has certainly died down over the years compared to what it use to be or should be. I'm sure the killing of the cw test helped. Of course on CW test weekends it gets quite lively. I like to work the CW late shift on 40m. There are clubs in my area of Tn. that just push ARES and not other areas or modes. RTTY has really died off here as well. There are many hams here who are members of groups who are planning and preparing for whatever might happen in 2012. So they get hams license for comminications and learn cooking, canning of fruit and vegs. and other areas. They don't really care for ham radio but just want to communicate in the event. I'd say their are about several hundred in middle Tn. One group is call the (9/12 ers). I'm teaching classes and pulling them into our club. We had about 35 of that group in Nov meeting. They are big on repeaters. That's great for them and really nice people too. Google 9/12 group. In2012 and 13, I want to pull them into normalcy of Ham Radio. Let me say I hope you all have a very good and happy Thanksgiving and pray for all be here in the coming years. 73, Roger, w4iv

Back in my early days (1963), almost every evening, 80 meter cw would be wall to wall occupied (all 300 kHz of the CW subband). I mean every kHz was occupied. Some evenings it could take you five minutes to find an unoccupied spot to call CQ. The phone portion was even worse. Likewise 40m and 20m.

Now you can tune 25-50 kHz and not hear a single signal.

Similarly 2m after the advent of repeaters (1970). Morning and evening drive time had at least a half dozen or more repeaters in steady operation (Cincinnati area). Now I can listen and rarely hear any use even during drive time. I was talking with a ham in Colorado who has a mountain top repeater that no one has used in months.

You say 10m is "full"????? I can still tune 25 or 50 kHz portions and not hear anything even in the popular segments although the band is very much open since I hear plenty of signals on the PSK frequency. I just tuned 28.6 to 29.1, a half megahertz, and didn't hear a single signal. The band certainly is not "full", at least according to my definition.

The only time I hear the bands "full" is on a weekend with a major contest. It used to be that way even without a contest.

True in some sense on commercial gear...but I recall having a surplus BC-348 that I bought for $50 (6 months allowance plus some birthday money from grandpa) and building my own transmitters from scavenged TV parts (great cause they had hefty power transformers anf flyback tubes) for only a few $$... If they ever figure out the time travel thing I am going back to 1963 the only thing I would miss is my PC but I think I'll get by :-)

From: Sebastian, W4AS
Topic: 20718 Message: 20740

Indeed. Not hearing activity on a certain band or a certain mode at a certain time, doesn't mean that activity is low.

A prime example is 2 meters. Many hams will say they no longer hear a lot of activity on the 2 meter repeaters anymore. That may be true, but what they may not realize is how many signals are on that band.

One example is the amateur satellites. The uplink for the most popular amateur radio satellite (AO-51) is on 2 meters. The US is in the footprint of that bird several times per day, but since we transmit on one band, and listen on another, many are not aware of those signals.

Anyone with a 440 FM rig, and a small home made antenna, can listen in on the fun. Anyone with separate 2 meter and 440 FM rigs, can join in on the fun. But be aware that AO-51 is very popular, and often times it has been referred to, as a zoo.

2 meters is also the most popular band worldwide for EME. Most hams believe they don't have the ability to make a contact via EME, but any ham with a 9 element beam, and a 100 watt 2 meter SSB rig, CAN make EME QSOs with several big gun stations in different countries. When conditions are good (roughly a few days of the month), it's often difficult to find a clear frequency on the lower portion of the band.

In the morning, 2 meters is also used to make meteor scatter contacts, up to roughly 1300 miles or more. That same 2 meter SSB 100 watt rig, and beam, will allow you to routinely make these long distance QSOs on a daily basis.

Some of us spend a lot of time building things, writing software, planning DXpeditions, reading this reflector, etc. I believe that all of those are examples of being active in the hobby.

It's human nature to believe that things were better when you were younger. Debating the merits of the licensing requirements of today, versus the requirements of years back, serves no constructive purpose for the future of this hobby.

True in some sense on commercial gear...but I recall having a surplus BC-348 that I bought for $50 (6 months allowance plus some birthday money from grandpa) and building my own transmitters from scavenged TV parts (great cause they had hefty power transformers anf flyback tubes) for only a few $$... If they ever figure out the time travel thing I am going back to 1963 the only thing I would miss is my PC but I think I'll get by :-)

Indeed. Not hearing activity on a certain band or a certain mode at a certain time, doesn't mean that activity is low.

A prime example is 2 meters. Many hams will say they no longer hear a lot of activity on the 2 meter repeaters anymore. That may be true, but what they may not realize is how many signals are on that band.

One example is the amateur satellites. The uplink for the most popular amateur radio satellite (AO-51) is on 2 meters. The US is in the footprint of that bird several times per day, but since we transmit on one band, and listen on another, many are not aware of those signals.

Anyone with a 440 FM rig, and a small home made antenna, can listen in on the fun. Anyone with separate 2 meter and 440 FM rigs, can join in on the fun. But be aware that AO-51 is very popular, and often times it has been referred to, as a zoo.

2 meters is also the most popular band worldwide for EME. Most hams believe they don't have the ability to make a contact via EME, but any ham with a 9 element beam, and a 100 watt 2 meter SSB rig, CAN make EME QSOs with several big gun stations in different countries. When conditions are good (roughly a few days of the month), it's often difficult to find a clear frequency on the lower portion of the band.

In the morning, 2 meters is also used to make meteor scatter contacts, up to roughly 1300 miles or more. That same 2 meter SSB 100 watt rig, and beam, will allow you to routinely make these long distance QSOs on a daily basis.

Some of us spend a lot of time building things, writing software, planning DXpeditions, reading this reflector, etc. I believe that all of those are examples of being active in the hobby.

It's human nature to believe that things were better when you were younger. Debating the merits of the licensing requirements of today, versus the requirements of years back, serves no constructive purpose for the future of this hobby.

Todd,

Welcome to the group. Been volunteering my time with (Hawaii) Department of Emergency Management (RACES) for a bit. Plus putting some time into Disaster Preparedness Events. Feels like I am actually doing something. Ham on a budget is ready and willing to assist. Just finished making my first J-Pole and putting together my HF antennae and testing.

Hello all,
I first got my Novice in 1969, and caught cycle 20. The bands were full of life, all the HF ones(that used to mean 160,80/75, 40, 20, 15 and 10). Like someone else said in here, they were as full as it is now only when a big contests such as SS and field day are going on. Every hour of every day, everywhere.

I remember clearly due to the rapid growth of popularity of personal computers and especially the Internet to the general pubic how they detrimentally effected hamming. There was a noticeable drop in activity during that period, hardly any new comers on the air. Didn't need to study up, pass a theory and CW test to get on-line.

My having being inactive 20 years or so (family, work) after getting back on the air I was shocked and alarmed, still am. Where did everyone go??!!!
Thought my antenna system had a problem for the first couple weeks back on!

And the CW activity!! Almost none on 40 meters during daylight hours!
I have tuned it many many times and heard not a single QSO, I have called CQ frequently for a half hour with no answer. Or the same three, count 'em, 3 guy's will reply. It's so silent it's creepy.

So a thought just crossed my mind, what am I doing here, typing?

See you on the air,
73,
Paul

>
> Back in my early days (1963), almost every evening, 80 meter cw would be wall to wall occupied (all 300 kHz of the CW subband). I mean every kHz was occupied. Some evenings it could take you five minutes to find an unoccupied spot to call CQ. The phone portion was even worse. Likewise 40m and 20m.
>
> Now you can tune 25-50 kHz and not hear a single signal.
>
> Similarly 2m after the advent of repeaters (1970). Morning and evening drive time had at least a half dozen or more repeaters in steady operation (Cincinnati area). Now I can listen and rarely hear any use even during drive time. I was talking with a ham in Colorado who has a mountain top repeater that no one has used in months.
>
> You say 10m is "full"????? I can still tune 25 or 50 kHz portions and not hear anything even in the popular segments although the band is very much open since I hear plenty of signals on the PSK frequency. I just tuned 28.6 to 29.1, a half megahertz, and didn't hear a single signal. The band certainly is not "full", at least according to my definition.
>

> The only time I hear the bands "full" is on a weekend with a major contest. It used to be that way even without a contest.

20746. Tower Restrictions

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-23 00:54:59 UTC
From: Joe
Topic: 20746 Message: 20746

A question.

When a county has restrictions on towers. And their definition of a
tower is,,,

(9) TOWER. Any structure that is
designed and constructed primarily for the purpose
of supporting one (1) or more antennas, including
guy towers, monopole towers and self-supporting
lattice towers, including any support thereto.

OK, Now if the whole "Tower" is used as an antenna. as in a Hy-Tower,

http://www.dxengineering.com/images/examples/K0OK-HyTower_example.jpg
It looks like a tower, But it actually is an antenna. Not a tower that
is supporting 1 or more antennas.

Or to stretch this further, How about
a regular "Tower" that has a tribander on it. that again the tower is
loaded say shunt fed and the tribander is the capacity top hat., again
the tower is the antenna and not a tower.

http://1.bp.blogspot.com/_tWcsnP09Wj8/TDPne6Dco7I/AAAAAAAAB0Y/UEpW7fV5n10/s1600/The-details-of-the-shunt-feeding.png

It is an antenna not a tower true?

This part: "designed and constructed PRIMARILY" has a great big hole!

What if you apply for, and obtain a permit for a chimney, or even a flagpole, and after it's inspected and approved, place an antenna on it? The primary purpose in this case, was clearly not for an antenna.

Yes I would say this has a big loop hole, I would also look at where you live, if you dont live within the city or town limits, most bylaws do not apply to unincorporated parts of those citys or towns. This would falls on the county's bylaws.
You see I live in a unincorporated part of town, with in the town limits you can't burn leaves due to the town pickup of those leaves... But here we, so we go by county law which says we can, to a point. I would check into that. As far as antenna if a structure was not ment to hold an antenna and you put one on the city/town can't say anything but if you create one of those things that are ment for an antenna then... well you get the jist.

Convince you? Seems to me that “you” were never covered in the Ham classes
I just recently took and passed the test for. Sorry fellows, but I do have other activities,
not the least of which is poor health. It has been 30 plus years since I listened to 10 meter
sideband prior to now, so I can’t say how it has been of recent times. My fixed income
and inability to do a lot of outdoor antenna work myself limits my on air time at present.
But I, as well as many others, will get there. I can’t jump in and do things in a day, but maybe
I can in a week or a month. And if I am struggling to get these things done, I am not sitting
in the shack making my presence on the air known. I would like the same considerations
that were given to others when they started in the hobby, so that one day I can reflect on
how changes have occurred. We as new Hams are no better or no worse than the others
who now call themselves old timers. Too often life gets in the way of what we want, but if we
strive to the same goals, maybe sooner or later we do get there.

Sorry, Sebastian, I don't see that we are alienating anyone. I do think it is a legitimate concern that although our licensed numbers are almost 3x what they used to be, actual on the air activity is down. IMO, the licensed numbers hide the actual decline of the hobby.

Now if someone wants to convince me that we really have more people active, be it experimenting on short distance 1200 and 2300 MHz work, or in other activities that I don't see, that would be great.

Thank GOD for oldtimers. We all need an 'Elmer' to help us out. The book knowledge and experience takes a looooooooong time to catch up to our Elmer who helps us get a rig, hook it up, learn on the air practices. The only book close is 'Understanding Amateur Radio' from the ARRL. eg Was running 70 watts AM calling my friends in town and they couldn't hear me. I called my Elmer and he came over. After laughing for 5 minutes, he showed me I had the microphone hooked to the antenna jack and the antenna to my microphone connector. Don't say 10-4, say Roger, on and on it goes.

Maybe you all should get a Chat Room going, this is about Antennas, it
will help keep our e-mail box cleaner. Some of us belong to other groups and
within 5 hours 32 are not about Antennas or anything pertaining to the Main
Subject.

Thanks ED kj4fgi

The ham licenses at a all time high. It is a no-brainer. If you lower the bar by eliminating the code test and dumbing down the theory, of course you are going to get more hams. Better, more qualified hams, that is open for debate.

Convince you? Seems to me that “you” were never covered in the Ham classes

I just recently took and passed the test for. Sorry fellows, but I do have other activities,

not the least of which is poor health. It has been 30 plus years since I listened to 10 meter

sideband prior to now, so I can’t say how it has been of recent times. My fixed income

and inability to do a lot of outdoor antenna work myself limits my on air time at present.

But I, as well as many others, will get there. I can’t jump in and do things in a day, but maybe

I can in a week or a month. And if I am struggling to get these things done, I am not sitting

in the shack making my presence on the air known. I would like the same considerations

that were given to others when they started in the hobby, so that one day I can reflect on

how changes have occurred. We as new Hams are no better or no worse than the others

who now call themselves old timers. Too often life gets in the way of what we want, but if we

strive to the same goals, maybe sooner or later we do get there.

Sorry, Sebastian, I don't see that we are alienating anyone. I do think it is a legitimate concern that although our licensed numbers are almost 3x what they used to be, actual on the air activity is down. IMO, the licensed numbers hide the actual decline of the hobby.

Now if someone wants to convince me that we really have more people active, be it experimenting on short distance 1200 and 2300 MHz work, or in other activities that I don't see, that would be great.

I enjoy V/ UHF in the car and HT at home - I participate in at least a couple of HF contests - QRP in USIslands - and starting out in some NASOTA activities - enjoy making my own HF antennas. Fairly active all the way around but it's not an every day thing - as is with most hobbies (sorry one guy doesn't like the term hobby) but it is FUN ! and you meet alot of people you wouldn't normally meet . maybe next I'll try PSK-31 cause I stink at CW

Jay NX2C

You know, there are experimenters that have a license to test their projects on the air. There are QRPers who focus on one frequency. There are hikers and mountain climbers who get on the air and there are those who are happy to make 1 QSO or 2 per day. Most of these guys are not obliterating the airwaves.
Then there are the VHF guys who are not HFers and the VHF bands are not hopping 24/7 due to limited propagation.

Best Regards

From: Frank Kirschner
Topic: 20746 Message: 20759

I would say that you are technically correct, and if I were evaluating permit applications for your local government, I'd say that an antenna is not a tower, because it doesn't *support* an antenna, it *is* an antenna. However, that distinction would probably be lost on the average government clerk. The Hy-Gain vertical looks like a tower supporting a vertical antenna or two at the top.

You might get away with one of the 43 ft vertical pole antennas or something like that that clearly isn't "tower-looking."

Let us know how it comes out.

I'm with you, Larry. I'm grateful when an "old-timer" offers a helping hand. After four years in Amateur Radio (and a newly minted General), I'm finding that not having had an Elmer (until recently) really kept me from enjoying more of this hobby.

Old timers: be an Elmer. Mentor the new hams. Give presentations at local clubs showing those new Technicians the bigger world of HF. Teach classes that include the theory beyond just learning the answers to the questions in the pool.

The more we invest in people, the better Amateur Radio will be.

Doug W4DDA

PS. Although I'd looked into getting a license in the 80s, it wasn't until 2008 at a National Weather Service "Skywarn" storm spotter session that got me motivated to get a book and take the test. About half of the storm spotters at that session were Hams.

Supplying any power to anything that can be touched can be a safety danger. OET-65 has a specific section devoted to HAM radio, Maximum Permissible Exposure is part of all HAM's teaching
and the license tests for quite some time for all USA HAMs General class and above, is is very a
serious matter.

Or go in the next garden-shop and see for "amevo-rosenclips"

(Nederland brand name ...amevo sells all what you need for the
Garden)

Maybe name in your country is different ... but sure something similar can
be found on your location
(or just call amevo and order them from the Netherlands)

I made a folder in the photo-section (dg9bfc)

There I uploaded a picture from these clips

Rosenclips.jpg

They are use in agriculture to hold plants vertical (on wires or lines)

They are available in different size (so different impedance of ladderline
could be made from them)

And they cost almost nothing !!!

Subject: [ham-antennas] Re: ham licenses-at-all-time-high

I'm with you, Larry. I'm grateful when an "old-timer" offers a helping hand. After four years in Amateur Radio (and a newly minted General), I'm finding that not having had an Elmer (until recently) really kept me from enjoying more of this hobby.

Old timers: be an Elmer. Mentor the new hams. Give presentations at local clubs showing those new Technicians the bigger world of HF. Teach classes that include the theory beyond just learning the answers to the questions in the pool.

The more we invest in people, the better Amateur Radio will be.

Doug W4DDA

PS. Although I'd looked into getting a license in the 80s, it wasn't until 2008 at a National Weather Service "Skywarn" storm spotter session that got me motivated to get a book and take the test. About half of the storm spotters at that session were Hams.

20771. #18 vs. #14 window line

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-24 06:41:01 UTC
From: s3hampton
Topic: 20771 Message: 20771

Is there an advantage to use #14 over #18 window line? (Both examples would be 450 Ohm impedance.)

Is there an advantage to use #14 450 Ohm window line over #18 300 Ohm window line?

My problem: I have a loop antenna that operates POORLY on 75 meters, compared to my original loop and a simple dipole. (The new loop is about 10 dB worse than the original loop or a standard dipole!)

I am trying to figure out why this is!

My new loop is remote, so I have 220 feet of #18 wire type 300 Ohm window line feeding this new loop.

My older (original) loop is about the same height, but is fed with only 50 feet of 450 Ohm window line.

BOTH loop's wire is made with #14 THHN stranded wire.

- The new loop's feed-line DC resistance is slightly higher than the wire in the loop

- The original loop's feed-line DC resistance is less than HALF of the wire in the loop

Please read the information below. The answer to my puzzle is maybe more obvious that I have ignored??? (Is this is case of a simple voltage divider that is causing 2/3 of the power to be absorbed/dissipated by the feed-line???)

My point is that folks had said that 300 Ohm line was just as good as #14 450 Ohm line, and that the smaller 300 Ω stuff was even nicer as it has lower wind resistance, etc.

But, I look at the resistance in the LOOP itself, as compared to the resistance in the FEED-LINE... Boy, this is looking not as good as one might think! -Could my problem be this simple???

My NEW 1000 foot loop is fed with 220 feet of #18 300 Ohm line:

```
1000' #14 = 2.6 Ohm <-(Loop's wire)
440' #18 = 2.86 Ohm <-(Feed-line's wire)
-------------------
Total = 5.46 Ohm (Theoretical)
```

- My ORIGINAL 540 foot loop (the original "North loop") should be 1.4 Ω for the 550 feet of #14 wire, plus the 50 feet (100 feet of WIRE, total) lead-in, assuming this wire to be #18 size:

```
540' of #14 = 1.4 Ohm <-(Loop's wire)
100' of #18 = .65 Ohm <-(Feed-line's wire) (This actually might be larger wire)
-------------------
Total = 2.1 Ohm (Theoretical)
```

The interesting point is that the DC resistance ratio that I am seeing:

- The new loop's feed-line DC resistance is slightly higher than the wire in the loop

- The original loop's feed-line DC resistance is less than HALF of the wire in the loop

What I am getting at is the possible contributing factor might be the DC resistance of the two feed-lines, compared to the resistance of the wire in the actual loop antenna-wire:

- For the new loop, the 220 foot run of (#18) wire computes to about 3 Ohms
- The same 220 foot fun of #14 wire computes to 1.144 Ohms.

Now I probably have it all wrong but a doubling of resistance must be even higher inductance and a doubled R is a 4 fold reduction in I so that is 6db so given a bit for the inductance perhaps 10db is about right?

Wiser heads than mine will know for sure

If it's a half a meter above the roof it should not effect it's operation.

Performs worse AT WHAT DISTANCES? The two may have very different radiation patterns/ angles.

Although relative DC resistance may be indicative or RF resistance, remember that due to skin effect at RF frequencies, they two are very different. I would guess that your issue is somewhere else, with radiation pattern, tuning, height above ground, etc.

Topic: 20771 Message: 20775

Mike

1) Don't immediately assume that the difference in performance is due to the feed line. Given the size difference , The two antennas will have entirely different performance characteristics. Radiation patterns, nulls , angle of take off will all be different rather like comparing apples and oranges and bigger is not always better. Are you feeding both loops in the middleat the bottom ? at the corners? on the sides? all will make a difference in take off angles. Bottom feed will give horizontal polarization (high angle take off. local communication) feeding at the sides will give you vertical polarization with lower take off angles suited for distant communication...and the list goes on

2) if the large loop is significantly mismatched to the 300ohm line the losses in the feed line will be higher to be sure .If we are talking 300ohm solid dielectric (no windows, i.e. what we used to call TV twin lead) vs 450 ohm window line the losses will be higher in the 300 ohm line. Assuming the line is matched to to the loop (unlikley) the losses at 3.5 MHz at 200 feet for the 300 ohm, line are on the order of .5dB (not much) vs less than .1db for the 450 Ohm window line. lets say the loop looks like 1200 ohms at the feed point .

3) For the sake of argument lets say the big loop has a feed point impedance of 1200 ohms this would give an SWR of 4:1 on the line at 3.5 mhz the losses due to the SWR at 3.5 MHz are less than an additional 2db (and S unit is 6db) so it is unlikely that you will be able to hear the difference.

4) the higher you go in frequency the greater the losses this same example above at 28 MHZ will have losses in the order of 6-10 db now you can begin to tell the difference at bit.

Before you jump to any conclusions about feed lines I would want to measure the feed point impedance and probably model the loops using a antenna modeling (EZNEC etc) program at the frequency of interest. to get an idea of what is probably really going on. My money is that the differences you are hearing have more to do with the radiation pattern differences of the two antennas first and feed point matching 2nd ...line loss while slightly higher with 300 twin lead is a distant 3rd

Good luck
73

There are a few web pages that show how to do this.
http://www.hamuniverse.com/multidipole.html It doesn't show the WARC bands but you can simply substitute those for the ones it shows or add them to the antenna. I have a 75/80 /40 meter fan dipole and it works on most frequencies. Not working on 6 or 20 meters without an external tuner.

More pages, I just put in fan dipole in google

http://www.hamuniverse.com/ae5jumultibanddipole.html

How to make it for your frequency http://www.eham.net/articles/12399

http://wa2hip.com/jrpetro/My_Fan_Dipole_Projects.shtml

Hope you have fun with the hobby.

One of the things you can do is make the frequencies you do not have and make that antenna E/W and connect all the dipoles together. One feed line and a lot of frequencies. Sounds so good.

As I said in an earlier post I have been away from this hobby almost 10 years. One of the things I enjoy most is tinkering with and designing antennas ...For may years I ran the old DOS based versions of EZNEC but that was 10 years ago with then 10 year old software :-) . I cant even find the disks anymore and I suspect the technology has moved on .

Here is my question what software do you use and like for antenna modeling? MY apologies if this has been beat to death in the past, but going bAck through the email archives the last two years yielded nothing in my search on comparative comments on modeling software ...

If you have EZNEC-5+ was the extra segments worth the money over EZNEC 5.0)?

Is EZNEC really the only game in town these days or have other contenders emerged?

20783. Welcome back to the hobby Dave

Yahoo group: ham-antennas (2011-08 — 2011-12)

From: Robert KB6QXM
Topic: 20783 Message: 20783

Dave,

10 years away from the hobby, that's nothing. LOL. I have been without a station for 21 years.

At least I came back when the solar flux numbers are going back up.

Subject: [ham-antennas] Antenna modeling software ????

As I said in an earlier post I have been away from this hobby almost 10

years. One of the things I enjoy most is tinkering with and designing

antennas ...For may years I ran the old DOS based versions of EZNEC but

that was 10 years ago with then 10 year old software :-) . I cant even

find the disks anymore and I suspect the technology has moved on .

Here is my question what software do you use and like for antenna

modeling? MY apologies if this has been beat to death in the past, but

going bAck through the email archives the last two years yielded nothing

in my search on comparative comments on modeling software ...

If you have EZNEC-5+ was the extra segments worth the money over EZNEC 5.0)?

Is EZNEC really the only game in town these days or have other

contenders emerged?

Dave

From: Benjamin Straw - KC9UNS
Topic: 20781 Message: 20785

I would say mmana-gal from http://hamsoft.ca/ but is is a bit confusing to use. Now http://www.ve3sqb.com/ has some good software for different types of antennas that are easy to use for the novice antenna builder.

All,

Thank you for your links. I will attempt to build an antenna for what the DX-cc is not built for. 160, 60, 30, 17 and 12.

That will give me the other 5 bands I do not have on the DX-cc.

20790. Re: [ham-antennas] Fan dipole for 60, 30, 17 and 12

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-24 19:21:23 UTC
From: dean
Topic: 20782 Message: 20790

My 75/80 and my 40 meter (inverted V fan dipole) works on 10, 12, and 15 meters without a tuner. External tuner it works well on 17 and not so well on 20 meters but that is what the beam is for.

I have not tried 30 meters as of yet. That is just two wires up. 75/80 N/S and 40 M E/W.

Of course what works for me might not work for someone else.

Happy Turkey Day

73, WY6L

20793. Re: [ham-antennas] Welcome back to the hobby Dave

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-24 20:22:59 UTC
From: Ed Stewart
Topic: 20783 Message: 20793

I got my first license K3SFA in 1961 and was active for many years here in Pa. I then spent time of inactivity in California working and let it laspe for over a year past renewal, got the novice call of KN3BFO , Used it up without going any farther, Last Monday I took the Tech and passed then the general test, but missed the general by two questions. I am waiting for the new call sign now, so will be back on the air soon, going for the general and or the advanced in spring. Ed

From: WA8JXM
Topic: 20782 Message: 20794

Nothing against a fan dipole, but when you really want to cover all ten bands, I tend to favor a single dipole on the lowest band fed with open wire to a balun and tuner.

If your rig has a tuner, it might well match the load on all bands. Run a short section of coax outside to the balun and that simplifies the installation.

Actually for ease of feeding, something a little shorter (or longer) than a full half wave is easier to match.

Ken WA8JXM

Date: 2011-11-25 00:20:28 UTC
From: Ron Youvan
Topic: 20771 Message: 20795

s3hampton wrote:

> Is there an advantage to use #14 over #18 window line? (Both examples would be 450 Ohm impedance.)

You an get AWG 14 wire at the home improvement stores (in 500' spools if you wish) and use "ladder snap" insulators to make open wire feed line, they only fit #14. This is 600 Ohm line!

> Is there an advantage to use #14 450 Ohm window line over #18 300 Ohm window line?

Slightly lower loss (450 Ohm) but 600 Ohm line made with AWG 14 wire and "ladder snap" insulators
will have lower loss and wind loading and be less visible. (if white wire and insulator are used)

I have a 160M dipole fed with coax and the tuner in my radio tunes it and it works just fine.

20798. "dumming down"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-25 03:22:29 UTC
From: Dale H. Cole K8TS
Topic: 20798 Message: 20798

Boy, do I have a dislike for that attitude.

Let me explain:

As we grow older (first license in '72,)we have to expect change. We used to have the opportunity to hold more than one license. We used to have to sign /* and change our call every time we moved. The FCC, even as it creeps along, makes changes. The new hams that enter our ranks are not necessary "dummer" than we are.

We have had to learn more to keep up with the new hams of today. Remember when "flip flops" were a shoe, and a "diode" was when you passed away?

Were we tested on computer packet systems? How about "usb" or "com ports". No. We had to learn them. The new ham is already using them, or in many cases that is past history that they used years ago, and since then have moved on to even higher technologies. In my time I do not ever remember being tested on Smith Charts--I go to the new hams to interpret (and sometimes have drawn) for me. How about the "Doppler shift", not on the old tests, now eight grade stuff for those coming up. Who remembers apogees on their old tests. Bet some of the people in this group have had to ask someone (newer ham?) about them.

Had to throw up a tower in the past? Now we have to use (whether we like it or not) an engineering inspector to make sure we do not shoot our self in the foot. Sometimes they might be right. Laws change. Technology changes.

CW? see how many competitors you have this weekend in CQWW CW. It is supposed to be dead. DSB? It would never be replaced by that new SSB.

Sometimes us "old roosters" have to be kicked in the "a**", told that what we said was impossible, and watch how easily it can be done by today's standards. "Dummer no, Smarter, yes.

Remember that the next time you sit behind your D-104 chatting on 80 with your Drake, while texting a friend 2000 miles away on your cell phone.

Just My Humble Opinion,

Dale K8TS

(good in QRZ, not sure about The Flying Horse)

Maybe you could spray paint part of the baloon silver and use it as the antenna. Or you could use a wire(s) guy wire as the antenna.

You an get AWG 14 wire at the home improvement stores (in 500' spools if you wish) and use
"ladder snap" insulators to make open wire feed line, they only fit #14.
This is 600 Ohm line!

> Is there an advantage to use #14 450 Ohm window line over #18 300 Ohm window line?

Slightly lower loss (450 Ohm) but 600 Ohm line made with AWG 14 wire and "ladder snap" insulators
will have lower loss and wind loading and be less visible. (if white wire and insulator are used)

Or use mmana (also freeware)
...
I think mmana is a bit easier to use and understand
But that□s my personal thoughts

1.8 x 3 = 5.4

The same as on 15m and 40m

7 x 3 = 21

I am guessing that it should work (with a bit of tuning needed)

20804. AW: [ham-antennas] Antenna modeling software ????

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-25 09:10:07 UTC
From: Siegfried Jackstien
Topic: 20781 Message: 20804

I use mmana

Easy to use and freeware (only pro version costs money)

I made LOTS of designs with the soft ... and there are a few hundred
antennas ready in the antenna folders (so easy to start with)

Soft can be found here:
http://hamsoft.ca/pages/mmana-gal.php

.....

http://groups.yahoo.com/group/MMANA-GAL
http://groups.yahoo.com/group/MM-HAMSOFT

Two user groups were you can upload problematic designs or get help if you
have problems with using mmana

There are a few limitations were you have to be careful with arranging the
wires (cause mmana uses the mininec machine) but on most things the soft is
accurate ...

Any questions? Feel free to ask

I use it too. My thoughts are that 4NEC2 is a bit easier to use. :-)
4NEC2 now has the geometry editor (graphical versus entering line segment data) which I find in some cases to be a little more straightforward. Maybe MMANA has a geometry editor but I've never found it if it does.

Good news is there are both of these fine software packages available at no cost!

I understand Dale and sometimes we new hams are to quick to stick the sword in. I am one ham who tried to understand everything I could on all three levels of testing that I took. Most of it I did understand and am ashamed to admitt, but forgot some of it because of lack of use and todays busy schedules. One thing I will disagree with is when a new ham says there are no good elmers out there for them. I must have about 4 great elmers that have really helped me out. I ask them questions all the time and if they look at me like im stupid I tell them remember where I came from, born in the late 60s HI HI. They are always very eager to help and teach me.

I remember at a club meeting some of my elmers were talking about RTTY and talking about the machines and hardware they used for it. I had no clue how the machines worked and never seen one, other than pictures. So when I stuck my nose in of course there was a little teasing going on but all in good fun. Anyways when I said I would like to see such a set up none of them had one. Couple days later the one elmer gave me a call and told me to come over when I had a chance. Went over and there it was. RTTY station all set up. Boy was that fun. That is a good Elmer. It is because of my Elmers that I am so very fond of the CW mode and have progessed at it so well. So sometimes we new hams have to read between the lines and so often we don't. Tony

The old Teletype machines were absolutely amazing: all the complex mechanical work they did....just to print a single character! A true Rube Goldberg contraption that worked amazingly well.

As for "dumbing down", well heck, that's been complained about forever, at least since the FCC introduced the novice and tech licenses (in the 1950's?). BTW, back then the Tech exam was the same as the General exam except that the code requirement was 5 wpm instead of 13. Taking the Tech exam was an easy practice test for taking the General.

In reality, today's exams probably requires answering more technical questions than it did 40 years ago. However, having the question pool published does allow people to study and memorize the correct answers without understanding the questions or answers. (I am not saying that everyone does that, but it is possible I guess.) It used to be prohibited to publish the actual questions and answers and the license guide just listed the types of subjects that the person would face. So today we have some people who got the answers right but didn't understand what they were answering.

OTOH, the whole formal Elmer concept came along 10-15 years after I got my license. I didn't have any mentors to help. I spent many, many hours reading the Handbook and Antenna manual and old magazines on my own.

I passed my Extra back in 1967 in front of an FCC examiner, including copying and sending 20 wpm CW (1 minute of 100% copy required, no guess work allowed). Could I pass the current exam? Probably not without studying. But what I do know now is real knowledge, not canned answers to canned questions. And maybe that's the real issue all the time: the older ops truly know what they know just like new people today will really know what they know 30 or 40 years from now.

I had a complete Model 15 RTTY station , all the electronics , cables and things that went with it and about 10 boxes of the printer paper . donated it all to the Texas radio room restoration project when I left houston . was a good setup but was that printer ever noisy and the receiver drifted unless it was on for a couple of hours before you tried to use it .

When got my licenses, all the way from Novice in '79 to Extra in '81 plus my Commercial Radiotelephone in '82, I sat every single exam after Novice at the FCC "Dungeon Of Doom" on Dearborn St. in the Dirksen Federal Building, Chicago. By that time ham licenses had already migrated to multiple-guess, but the Commercial exam was still draw schematics and turn in your scratch sheet...

I didn't have an Elmer. I had a 1964 Handbook and early-60's copies of "Learning The Radiotelegraph Code" and "How To Become A Radio Amateur", a trash-picked complete set of QSTs from 1945-1975 inclusive, homemade code practice tapes, and a good friend who got his licenses and his various upgrades the same time I did.

IMHO the biggest blow to Amateur Radio was the institution of the VE program...I used to be a VE, specifically the guy who gave CW exams...that lasted til the boss VE insisted I pass people who couldn't copy at all for reasons I disagreed with...

I'm pretty sure we did not have to draw schematics in 1963 but we had to answer questions about them. But you are probably right that the old timers back then thought the tests were dumbed down since people didn't have to draw the schematics.

I took my novice, tech and general all in 1963 (June, Oct, Nov) and I'm pretty sure it was multiple choice then. However the actual questions were not allowed to be published, just the general type of questions.

Subject: AW: [ham-antennas] Fan dipole for 60, 30, 17 and 12

1.8 x 3 = 5.4

The same as on 15m and 40m

7 x 3 = 21

I am guessing that it should work (with a bit of tuning needed)

The EZNEC software does the same job as the NEC2 software. The difference is that EZNEC provides a convienient interface with a GUI that allows you to focus on the antenna and not on the program. The input data part has been made as simple as possible without limiting the programs functions. The output is in a form that needs little if any further manipulation to understand.

If the interest is there, download the demo and give it a try. A lot of experimenters don't really need anything else. I probably don't need EZNEC 5+ but it just don't cost that much more to lose the limitations.

If you are inclined to get down to the bare metal operation, NEC2 is probably available on the internet somewhere for free. It is public domain. When I investigated it I decided it was too much like a trip back in time to the punch card era and not something I would would care to revisit.

I believe Roy has an offerring that uses the NEC4 package but That is well beyond my needs and budget!

For my purposes, EZNEC has paid for itself many times.

I have teh Q & A manual from ARRL here from 1963.
We had to draw schematics.

Not much multiple choice to be memorized, at least in 1963

I'm pretty sure we did not have to draw schematics in 1963 but we had to answer questions about them. But you are probably right that the old timers back then thought the tests were dumbed down since people didn't have to draw the schematics.

I took my novice, tech and general all in 1963 (June, Oct, Nov) and I'm pretty sure it was multiple choice then. However the actual questions were not allowed to be published, just the general type of questions.

All antennas are at an average of 35 feet above the ground.

The NEW (large) loop is completely free of the trees.

The old (but GOOD) loops are IN THE TREES!

Yes, I have considered the very real, and sometimes dramatic lobes that any loop will have. I still see the "differences" between the two 1-WL loops, the 2-WL loop (this is the NEW one) and the standard dipole.

ALL antennas are at an average of 35 feet, again, including the dipole.

The two 1-WL loops are equal performance, for receive and transmit, for the most part. (I do see the effects of the LOBES, of course...)

The dipole is almost as good as the two original 1-WL loop antennas.

The NEW (large) loop is the one that is the poorer performer.

My main (worst) "loss" or lower-than-the-original-1-WL-loops is seen on 75 meters. This is after a lot of testing, TX and RX, while being able to INSTANTLY switch between the antennas via a remote relay box.

I still see a difference on 20 and up, but the higher bands are not as dramatic. -But on the average, still noticeably worse on the BIG LOOP as compared to any of the other three antennas.

To recap:
- The large (new) loop is fed with 220 feet of #18 window line.
- The other two loops are fed with 50 feet of LARGER-wire-size feed-line

Sure mmana has a graphical editor
And it is SOOOOO simple to use
If you ever used ANY paint software you know how to use it
Just click, hold button, move to other end and release button ... READY IS
THE WIRE 1 ...
It can be found under the edit menue

> apples and oranges and bigger is not always better.

Yes, very true! I have expressly been watching for this lobe-factor. As a result, I have been "averaging" the overall effects or performances...

> Are you feeding both
> loops in the middleat the bottom ? at the corners? on the sides? all
> will make a difference in take off angles.

In all cases, the antennas are HORIZONTAL, so it is not possible for me to feed from the BOTTOM.

All loops are fed at a corner.

The two 1-WL loops are 4-sided, and not square.

The NEW loop (the PIG!) is a five-sided loop that is completely free of the trees; It is in an open field, whereas the other two loops are actually IN THE TREES.

Bottom feed will give
> horizontal polarization (high angle take off. local communication)
> feeding at the sides will give you vertical polarization with lower take
> off angles suited for distant communication...and the list goes on
>
> 2) if the large loop is significantly mismatched to the 300ohm line the
> losses in the feed line will be higher to be sure .

I can feed the antenna with, or without a tuner. Some of the figures follow; These are the points (in Mhz) where I see a genuine 1:1 SWR, with no tuner involved at all! -Except where noted.

1.85 = 1:1
3.75 = 1:1 (3.86 = 2.2:1) (3.99 = 3.3:1)
14.3 = 1:1
18.3 = 1.3:1
21.3 = 2:1

24.95= 2.8:1
28.4 = 1.8:1

> If we are talking
> 300ohm solid dielectric (no windows, i.e. what we used to call TV twin
> lead) vs 450 ohm window line the losses will be higher in the 300 ohm
> line.

I am using 300 Ohm window line that is actual WINDOW LINE, not TV-twin-lead. It has (per the supplier) $18 stranded wire, and this seems to be close, by my un-calibrated eye...

Assuming the line is matched to to the loop (unlikley) the losses
> at 3.5 MHz at 200 feet for the 300 ohm, line are on the order of .5dB (
> not much) vs less than .1db for the 450 Ohm window line. lets say the
> loop looks like 1200 ohms at the feed point .

Ratz. I have indeed seen this. My only "hope" was to assign the possible LOSS to the DC resistance of the fed line.

In the case of the BAD loop (this is the new, 1000 or so foot antenna), the DC resistance is about TWICE the resistance of the #14 wire that makes up the radiator of the new loop.

In the case of the two GOOD (1-WL) loop antennas, the DC resistance of the feed line is HALF of the resistance of those loop antenna's #14 radiator wires.

>
> 3) For the sake of argument lets say the big loop has a feed point
> impedance of 1200 ohms this would give an SWR of 4:1 on the line at 3.5
> mhz the losses due to the SWR at 3.5 MHz are less than an additional 2db
> (and S unit is 6db) so it is unlikely that you will be able to hear the
> difference.
>

I am getting a LOT lower SWR that what you have suggested as an example. (Please see my figures above...)

> 4) the higher you go in frequency the greater the losses this same
> example above at 28 MHZ will have losses in the order of 6-10 db now
> you can begin to tell the difference at bit.
>

This is the funny part: As I go UP in frequency, the large loop is approaching what I see and experience with the original (the GOOD loop) antennas!! (This is for both for RX and TX, of course!)

This is just the opposite of what you had offered...

>
> Before you jump to any conclusions about feed lines I would want to
> measure the feed point impedance

I cannot do this; No equipment, aside from the SWR meters that I have available...

> and probably model the loops using a
> antenna modeling (EZNEC etc) program at the frequency of interest.

I might be able to do this, but the big task would be trying to learn how to use one of these programs! -Not an easy task!

> to
> get an idea of what is probably really going on. My money is that the
> differences you are hearing have more to do with the radiation pattern
> differences of the two antennas first

This is a logical factor. And I have absolutely made myself aware of this. There is still no doubt that the new larger loop is simply a PIG.

I have a friend (not a HAM) who likes to toss a statement basically says if you put lipstick on a pig, it's still a PIG! Well, that's what I have here: A PIG.

and feed point matching 2nd

This is something that I have not addressed at all! But I do plan to, by dropping the loop, and attaching a very short feed line to the feed point. The antenna will be LOW on this one corner, but it will be at least CLOSER to offering me the true resonance of the wire.

> ...line loss while slightly higher with 300 twin lead is a distant 3rd

Yes, I agree.

But... (There's always that "But," right?)

I still am trying to clutch to the simple DC resistance of the FEED LINES as compared to the ACTUAL RADIATOR WIRE. Stupidly so? Most likely YES! But I am sort of out of ideas...

Thanks for your inputs!! 73; -Mike- KØJTA

Hi All,

I am one othe new hams, I have an electronics background and have been wanting to be a ham since I was about 7. I am now 63, I had a mental block about the code and this kept me from being a ham then life came along. I spent 21 yrs in the Navy. Then work came along. Since I retired I joined a civilian group called CERT and they offered me a chance to get my Tech ticket and I jumped for it. I am now a general working on her extra class.
I have been lucky and met several good Elmers that have gone out of there way to help all of the new Hams here. One thing we need to remember, I consider the older Hams as a super resource of information, it has helped me learn about building my own 2 meter antennas, and repairing my own gear.
Just remember, we can all learn something from each other, whether a new ham or an old hand at it.

The old Teletype machines were absolutely amazing: all the complex mechanical work they did....just to print a single character! A true Rube Goldberg contraption that worked amazingly well.

As for "dumbing down", well heck, that's been complained about forever, at least since the FCC introduced the novice and tech licenses (in the 1950's?). BTW, back then the Tech exam was the same as the General exam except that the code requirement was 5 wpm instead of 13. Taking the Tech exam was an easy practice test for taking the General.

In reality, today's exams probably requires answering more technical questions than it did 40 years ago. However, having the question pool published does allow people to study and memorize the correct answers without understanding the questions or answers. (I am not saying that everyone does that, but it is possible I guess.) It used to be prohibited to publish the actual questions and answers and the license guide just listed the types of subjects that the person would face. So today we have some people who got the answers right but didn't understand what they were answering.

OTOH, the whole formal Elmer concept came along 10-15 years after I got my license. I didn't have any mentors to help. I spent many, many hours reading the Handbook and Antenna manual and old magazines on my own.

I passed my Extra back in 1967 in front of an FCC examiner, including copying and sending 20 wpm CW (1 minute of 100% copy required, no guess work allowed). Could I pass the current exam? Probably not without studying. But what I do know now is real knowledge, not canned answers to canned questions. And maybe that's the real issue all the time: the older ops truly know what they know just like new people today will really know what they know 30 or 40 years from now.

Congrats and Welcome

Now that you can get on 2 meters, why not try 2 meter SSB (and CW) during Tropo Openings. You can works some states and many grids and if you are on the east coast, even a few local countries like Caribean, Mexico, Bahamas etc.

And, maybe we will see you on teh HF Bands in the future

Best Regards

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-25 23:44:03 UTC
From: mikethetuner
Topic: 20798 Message: 20823

I'd be lying if I said, as a young ham, that I didn't roll my eyes at the "walked to school barefoot in the snow uphill both directions" stories that my ham "elders/Elmers" shared about how they did so much operating with exposed high voltage, manual tuning from start to finish, built the rigs from scrap, and all that. Of course, now that I am one of "them" (licensed since 1976, had to pass all the tests in front of the FCC), I don't find their stories to be so far out after all because I have seen enough change in the 35 years since I got my Novice ticket to understand where they came from in that realm.

I had addressed this issue before in an earlier post regarding how the lack of fundamental knowledge in newer hams has increased since obtaining a license is now much earlier in the learning continuum than it was before. Granted, technology has advanced so far lately, and one can see this first-hand by opening the cover of any middle- to high-end transceiver made in the last 10-20 years--it's not "your grandpa's rig" anymore where it was easy to replace a bad component with plenty of elbow room. That being said, the realm of antennas is still wide open, and really about the last area of amateur radio left where anyone can experiment with very simple materials and concepts and build something to make the station better.

The basics have not changed, nor will they ever do so: the laws of nature cannot be repealed. Learn the basics, put the myths to rest, and above all, experiment with antennas! We don't learn if we don't try, and if it works, so much the better. And pass along your successes to the group as well as the failures. Learning should never, ever stop, and this group is a great resource for sharing and learning about ham antennas.

73, all!

Dean, if the Google Earth screenshots do not come through in this discussion group, please e-mail me direct: my callsign at ARRL.net and I will e-mail them direct to you.

Short answer: 75 degrees gets you crossing the USA, entering the Atlantic Ocean just north of Cape Hatteras, skimming the western bulge of Africa and passing just south of Madagascar.

Gibraltar, at the southern tip of Spain bears 48.9 degrees and is 5873 miles on the short path.

thanks I found a program that shows what I want. I just had to rephrase my question in google to find it. It shows the short path but I can follow it backwards and have the long path. The long path to Spain from here is over 19k miles according to one of the programs I'm using.

Subject: RE: [ham-antennas] Re: "dumming down"

When got my licenses, all the way from Novice in '79 to Extra in '81 plus
my Commercial Radiotelephone in '82, I sat every single exam after Novice at
the FCC "Dungeon Of Doom" on Dearborn St. in the Dirksen Federal Building,
Chicago. By that time ham licenses had already migrated to multiple-guess,
but the Commercial exam was still draw schematics and turn in your scratch
sheet...

I didn't have an Elmer. I had a 1964 Handbook and early-60's copies of
"Learning The Radiotelegraph Code" and "How To Become A Radio Amateur", a
trash-picked complete set of QSTs from 1945-1975 inclusive, homemade code
practice tapes, and a good friend who got his licenses and his various
upgrades the same time I did.

IMHO the biggest blow to Amateur Radio was the institution of the VE
program...I used to be a VE, specifically the guy who gave CW exams...that
lasted til the boss VE insisted I pass people who couldn't copy at all for
reasons I disagreed with...

The old Teletype machines were absolutely amazing: all the complex mechanical work they did....just to print a single character! A true Rube Goldberg contraption that worked amazingly well.

As for "dumbing down", well heck, that's been complained about forever, at least since the FCC introduced the novice and tech licenses (in the 1950's?). BTW, back then the Tech exam was the same as the General exam except that the code requirement was 5 wpm instead of 13. Taking the Tech exam was an easy practice test for taking the General.

In reality, today's exams probably requires answering more technical questions than it did 40 years ago. However, having the question pool published does allow people to study and memorize the correct answers without understanding the questions or answers. (I am not saying that everyone does that, but it is possible I guess.) It used to be prohibited to publish the actual questions and answers and the license guide just listed the types of subjects that the person would face. So today we have some people who got the answers right but didn't understand what they were answering.

OTOH, the whole formal Elmer concept came along 10-15 years after I got my license. I didn't have any mentors to help. I spent many, many hours reading the Handbook and Antenna manual and old magazines on my own.

I passed my Extra back in 1967 in front of an FCC examiner, including copying and sending 20 wpm CW (1 minute of 100% copy required, no guess work allowed). Could I pass the current exam? Probably not without studying. But what I do know now is real knowledge, not canned answers to canned questions. And maybe that's the real issue all the time: the older ops truly know what they know just like new people today will really know what they know 30 or 40 years from now.

One thing I will disagree with is when a new ham says there are no good elmers out there for them. I must have about 4 great elmers that have really helped me out. I ask them questions all the time and if they look at me like im stupid I tell them remember where I came from, born in the late 60s HI HI. They are always very eager to help and teach me.
>
> I remember at a club meeting some of my elmers were talking about RTTY

and talking about the machines and hardware they used for it. I had no clue how the machines worked and never seen one, other than pictures. So when I stuck my nose in of course there was a little teasing going on but all in good fun. Anyways when I said I would like to see such a set up none of them had one. Couple days later the one elmer gave me a call and told me to come over when I had a chance. Went over and there it was. RTTY station all set up. Boy was that fun. That is a good Elmer. It is because of my Elmers that I am so very fond of the CW mode and have progessed at it so well. So sometimes we new hams have to read between the lines and so often we don't.

From: Douglas
Topic: 20827 Message: 20827

All,

For months I've had major rfi issues in the house. Due to the layout of my yard, my Steppir Bigir vert is only about 10 feet from my house. When I would transmit, every hard wired smoke detector in my house would go off. This would happen at 300 watts and up.

Placed a split bead at every smoke detector, didn't solve. Finally placed a toroid on the ac line leaving the breaker with 6 wraps. So far, so good!!!

Comment from a no-code General as follows
IMHO
I always wanted to be a Ham, it is not my fault that the code was not required when I testes, however
I will make this statement "A new ham should be encouraged to learn CW". Comment some older seasoned hams make
are very discouraging to a new person that really wants to learn, not to made to feel inferior because he or she does not know code
Maybe these statements are not meant to be degrading.
But I am quite sure that this group and many others would like to see new call signs that can meet you on the Key or the Phone so lets encourage all new Hams to get that Key

Seeing as this thread WILL continue...I will throw my 3 cents in too.
I agree that the hobby was dying, and IF we didn't get some new blood fast..we stood to lose some choice frequencies. All for the "no-code" licenses, but as and old dog I still have one item I can't let go.
An EXTRA was always the goal, the best of the hams! (75M as the exception to that.)
I, to this day feel that there should be a mandatory "waiting" period before you can receive a Extra ticket. In the old days it was 5 years. I am willing to split the difference and make it 2 years. But I have personally seen (as a VE) people come in, test, and walk out with an extra license..and know less than my 16 year old cat does about ham radio. (No BS! my cat can't copy code..but see associates my call sign coming out of the speaker meaning Dad is going to go play on the radio, and usually beats me down the hall to the shack.)
I have been following this thread, even though it doesn't pertain to antennas. "Dumming down?" Maybe..maybe not. We NEED new hams!
But to cheapen the highest license, is like letting a 6 month Martial Artist student test for a black belt..no matter how talented he/she is!
BTW..I took code test at the Soldiers & Sailors Bldg. in Pittsburgh in 1977. The echo factor in the hall from the copy code was unreal!
But I got my General. Didn't get my extra till late 80's in Florida.
But as a Digital mode ham..I am still a Novice..got lot's to learn.
My 3 cents is up!
73,
Dave-KJ4PF

Jim, I would think it is the same as any other T-200-2B with the same height. If you take a look at my photo album you will see making baluns is a main part of the hobby for me. http://s1102.photobucket.com/albums/g453/KD0ZZ/

I follow the basic guide lines of a similar wind I find on the net but there is always a difference in what type of wire you use, I use magnet wire of difference gages, Teflon coated wire and/or speaker wire for different baluns I make. If I am trying something new I do a test wind and the check the point I get a 1:1 SWR reading at about 10 MHz, if you want to move the point of resonance it might require more windings if you want 160 and 80 the most and a winding or less for the 20 thru 10. Don’t believe the ads the lead you to think that the store bought balun is 1:1 across the bands. I use a analyzer but you can get by with your radio at reduced power and a SWR meter. That is the way I did it before I got a analyzer. I use a 200 Ohm carbon resistor for a 4:1 balun check, two of them for a 2:1 balun and so forth.

IMHO I have found that a duel winding Guanella 4:1 current balun gives me a wider range of good readings on a T-200 size core, as others say, your millage may vary.

As far as i know it is better to use 2 cores for a 1:4 current (NOT VOLTAGE!) balun ... so I would use BOTH of the cores, add 2 wires in parallel on each core, feed them in parallel on input (from coax) and connect output in series ...

“I follow the basic guide lines of a similar wind I find on the net but there is always a difference in what type of wire you use, I use magnet wire of difference gages,”

So I guess I should start with winding it per standard instructions (8 turns per section) test and adjust from there. Sounds like a plan to me , You almost need an antenna analyzer to experiment with baluns, well at least it has to make the process simpler... thanks, btw your photos provided some help to.

Greetz”

Does using both cores also improve power handling and/or band width?

Ok last comment before this gets pulled, I agree, I was one of those, I learned after I got my ticket, however
I made up my mind to learn
I was told by an old seasoned ham and one of my VE'S
License is the the beginning, now comes the learning
Nuff said

When I went to sit my Extra, by then the examiner I guess was getting somewhat used to seeing me every couple months, and greeted me on a first-name basis [deadpan]. When he finished grading my exam, he came out into the little anteroom and said "It's all over now", PERFECTLY dead-pan. I swear that guy never ever cracked a smile. He almost did when I went back for my Commercial. Almost.

You're right about the 'phones...I have a pair of the same kind here [Cannon Co. "Chief"] and they're still my preferred cw 'phones...

Subject: RE: [ham-antennas] Re: "dumming down"

When got my licenses, all the way from Novice in '79 to Extra in '81 plus my Commercial Radiotelephone in '82, I sat every single exam after Novice at
the FCC "Dungeon Of Doom" on Dearborn St. in the Dirksen Federal Building, Chicago. By that time ham licenses had already migrated to multiple-guess, but the Commercial exam was still draw schematics and turn in your scratch sheet...

I didn't have an Elmer. I had a 1964 Handbook and early-60's copies of "Learning The Radiotelegraph Code" and "How To Become A Radio Amateur", a trash-picked complete set of QSTs from 1945-1975 inclusive, homemade code practice tapes, and a good friend who got his licenses and his various upgrades the same time I did.

IMHO the biggest blow to Amateur Radio was the institution of the VE program...I used to be a VE, specifically the guy who gave CW exams...that

lasted til the boss VE insisted I pass people who couldn't copy at all for reasons I disagreed with...

Those old days:
We had to draw schematics of oscillators and amplifiers and do some pretty heavy math. Not much multiple choice to be memorized, at least in 1963

Subject: Re: [ham-antennas] Re: "dumming down"

The old Teletype machines were absolutely amazing: all the complex mechanical work they did....just to print a single character! A true Rube Goldberg contraption that worked amazingly well.

As for "dumbing down", well heck, that's been complained about forever, at least since the FCC introduced the novice and tech licenses (in the 1950's?). BTW, back then the Tech exam was the same as the General exam except that the code requirement was 5 wpm instead of 13. Taking the Tech exam was an easy practice test for taking the General.

In reality, today's exams probably requires answering more technical questions than it did 40 years ago. However, having the question pool published does allow people to study and memorize the correct answers without understanding the questions or answers. (I am not saying that everyone does that, but it is possible I guess.) It used to be prohibited to
publish the actual questions and answers and the license guide just listed the types of subjects that the person would face. So today we have some people who got the answers right but didn't understand what they were answering.

OTOH, the whole formal Elmer concept came along 10-15 years after I got my license. I didn't have any mentors to help. I spent many, many hours reading

the Handbook and Antenna manual and old magazines on my own.

I passed my Extra back in 1967 in front of an FCC examiner, including copying and sending 20 wpm CW (1 minute of 100% copy required, no guess work
allowed). Could I pass the current exam? Probably not without studying. But
what I do know now is real knowledge, not canned answers to canned questions. And maybe that's the real issue all the time: the older ops truly
know what they know just like new people today will really know what they know 30 or 40 years from now.

> I understand Dale and sometimes we new hams are to quick to stick the sword in. I am one ham who tried to understand everything I could on all three levels of testing that I took. Most of it I did understand and am ashamed to admitt, but forgot some of it because of lack of use and todays busy schedules. One thing I will disagree with is when a new ham says there
are no good elmers out there for them. I must have about 4 great elmers that
have really helped me out. I ask them questions all the time and if they look at me like im stupid I tell them remember where I came from, born in the late 60s HI HI. They are always very eager to help and teach me.
>
> I remember at a club meeting some of my elmers were talking about RTTY and talking about the machines and hardware they used for it. I had no clue
how the machines worked and never seen one, other than pictures. So when I stuck my nose in of course there was a little teasing going on but all in good fun. Anyways when I said I would like to see such a set up none of them
had one. Couple days later the one elmer gave me a call and told me to come
over when I had a chance. Went over and there it was. RTTY station all set up. Boy was that fun. That is a good Elmer. It is because of my Elmers that
I am so very fond of the CW mode and have progessed at it so well. So sometimes we new hams have to read between the lines and so often we don't.
Tony

I agree with Sigi about the two cores, I found the two core balun I made to be better the a single core and for further reference my twin rod balun turned out the best. Twin T200-2B,s would be going into the multi KW range. I used a few turns of RG-8X for my blocking choke but then I don’t run high power.

Rich, Kd0zz

Subject: AW: [ham-antennas] MICROMETALS T200-2B -VS- T130-2 Help

As far as i know it is better to use 2 cores for a 1:4 current (NOT VOLTAGE!) balun ... so I would use BOTH of the cores, add 2 wires in parallel on each core, feed them in parallel on input (from coax) and connect output in series ...
Greetz
Sigi
Dg9bfc
Ps add a choke below that with different material for blocking rf travelling down the coax shield

Comment from a no-code General as follows
IMHO
I always wanted to be a Ham, it is not my fault that the code was not required when I testes, however
I will make this statement "A new ham should be encouraged to learn CW". Comment some older seasoned hams make
are very discouraging to a new person that really wants to learn, not to made to feel inferior because he or she does not know code
Maybe these statements are not meant to be degrading.
But I am quite sure that this group and many others would like to see new call signs that can meet you on the Key or the Phone so lets encourage all new Hams to get that Key

20842. Re: [ham-antennas] long path

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-26 18:33:11 UTC
From: dean
Topic: 20821 Message: 20842

I downloaded DXview and it seems to do the job. I put in the callsign and it gives me a world of info. I believe my HRD log shows the distance but I wanted to see the path besides knowing the distance.

thanks

73, WY6L

Download free of charge DXAtas from DXAtlas.com
You can calculate any distance to anywhere and see Grey Line real time, Sunrise and sunset times etc etc.

The long path is aways 24,600 miles less the short path distance.

Ken

“Comment from a no-code General as follows
IMHO
I always wanted to be a Ham, it is not my fault that the code was not required when I testes, however
I will make this statement "A new ham should be encouraged to learn CW". Comment some older seasoned hams make
are very discouraging to a new person that really wants to learn, not to made to feel inferior because he or she does not know code
Maybe these statements are not meant to be degrading.
But I am quite sure that this group and many others would like to see new call signs
that can meet you on the Key or the Phone so lets encourage all new Hams to get that Key “

This argument has been going on since the first days of radio. As a matter of fact this is the same thing as your parents saying “In my day people didn’t act like that”. Code is gone so everyone needs to get over it. In the present time it would make more sense to say you need to type at 35 WPM to pass. That’ll leave a lot of the older op’s out in the cold. A lot of the worst behavior I’ve heard on the air involves hams that have been licensed for a long time squatting on a frequency with the “it’s mine” attitude. I just overheard what can best be described as a name calling children's fight this morning on 40 meters involving 2 extra’s, go figure, both were saying they were going to write the FCC about the other. Personally I should have recorded them and sent that to the FCC and both of them could have been corrected. I would just like us to act in a way that doesn't embarrass us to the rest of the world, no one seems to remember the fact that everything you say on HF is likely to be heard all over the world. I’m sure there must have been a time when you received information and encouragement from more experienced amateurs, it’s time we get back to a place where we remember we are all here because we have things in common or we wouldn’t be talking to each other...

Ditto! I for one get very tired of all the gabbing about this inconsequential subject. I got my licenses - Tech, General, & EXTRA - after 45 years of wanting to be a HAM now that I am retired I'm going to enjoy the hobby regardless of the opinion of some old timers who want to downgrade anyone with an Extra ticket and the lack of CW. By the way it is on my to learn list, but the more I hear of this bantering the less likely I am to want to join the exclusive club that is being professed. So please can we quit beating this poor dead horse. Sorry but I reached my limit.

“As far as i know it is better to use 2 cores for a 1:4 current (NOT VOLTAGE!) balun ... so I would use BOTH of the cores, add 2 wires in parallel on each core, feed them in parallel on input (from coax) and connect output in series ...
Greetz”

Does using both cores also improve power handling and/or band width?

Topic: 20798 Message: 20847

I've been reading this thread since it began a few days ago and haven't said a word until now.

I am 53 yrs of age and for as long as I can remember I wanted to get a license, even just a Tech license just to say I accomplished something in life.

What prevented me from doing it, the code prevented me.
Now you are all probably sitting there in your recliners or easy chairs saying how can this guy lay blame on the code and say that's what prevented him from getting a license. It's very easy, it's called a Learning Disability. People with certain learning disabilities do not understand some things no matter how hard you try tech them or no matter how hard they work to try and understand.

Well I was one of those kinds of people. I have been studying hard for the past year to get my Tech License and still have a ways to go.

I'm sorry to say this, but those old timers out here talking about the code this the code that and how the code should rule the air waves make people like me have second thoughts about wanting to be a ham. You make us feel like the lowest class

Just my 2 cents

Subject: Re: [ham-antennas] Re: "dumming down"

Ditto! I for one get very tired of all the gabbing about this inconsequential subject. I got my licenses - Tech, General, & EXTRA - after 45 years of wanting to be a HAM now that I am retired I'm going to enjoy the hobby regardless of the opinion of some old timers who want to downgrade anyone with an Extra ticket and the lack of CW. By the way it is on my to learn list, but the more I hear of this bantering the less likely I am to want to join the exclusive club that is being professed. So please can we quit beating this poor dead horse. Sorry but I reached my limit.

20848. EZNEC-ARRL

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-26 21:02:44 UTC
From: Scott & Sherry Souva
Topic: 20848 Message: 20848

Is the EZNEC-ARRL v5.0 that is included in the ARRL Antenna Book (22nd Edition) limited or disabled in any way? I am thinking purchasing the latest version of the ARRL Antenna Book and having EZNEC included sounds like a good deal. Is it too good to be true?

Allan,

I too have been reading this thread and I tend to agree with you. Not everyone has the ability to learn the code. It is like learning a language. Some people can learn it and some can't.
I was originally licensed in 1963 and eventually got my Advanced Class. Couldn't get past 15 WPM to take the Extra.

But, since 2005, I became an active DXer and I can copy limited code up to 35 WPM in my head. It just took a lot of listening and comparing what I heard with what I saw on the screen in the program CWGet.

But, I do not put people down for their inability to copy code. There are enough other modes available to keep a ham busy for a long time.

When I am in the shack, I have the headphones on and I will listen to a DXPedition sending out QSOs. I do this while I am busy with other things. What I hear is many different call signs being responded to by the DX Station. After a while I don't even think about what I am hearing. I just recognize call signs that are common in the DX community. Then after a while calls that I do not recognize start to pop into my head. It is a sort of code practice.

What is much more frustrating on the bands is not the lack of ability to use CW but rather the Internet DXers who click their mouse on a DX Cluster Spot to auto tune their radio. Too many times it happens that they did not look at the Cluster Spot comments that may say UP 5. So, they tune on top of the DX and then call on top of the DX.

The DX will frequently announce where he is listening. But too many of these internet DXers don't bother to listen before they call.

Best Regards

20850. Moderator Regarding: The "dumming down" Topic

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-26 22:52:44 UTC
From: van wd8aam
Topic: 20850 Message: 20850

Ok folks, some are getting tired of this
thread, as this is a Ham-Antennas Group, and the
posts should be about antenna subjects.

While this new record number of Hams is 'cause for celebration',
some posters have started denigrating others talents concerning
Ham radio code and electronics knowledge in general.
This is happening not only on this group, but several others as well.

This is not very nice, is tacky, and does NOTHING to make
others proud of being an Amateur/Ham radio operator.

The best of the comments have already been made,
(SEE the EXCELLENT comment below by KE7SBE in Arizona), and
there are others complaining of tiresome posts, so it's time
for the moderator to jump in and terminate this thread.

Please RETURN to Antenna Subjects and restore the reflector
to appropriate postings.

Thank You
Van Lincoln
moderator

I also couldn`t grasp the code back in the 80`s when my son who at the time was the youngest person to get his tech license in his club he took to it like a duck to water as they say ,I tried got frustrated and gave up, he looked at me a few years ago and said you know you dont have to know morse for your ticket anymore right? I immediately got my hands on a manual, went for the tech ticket , worked at the general class book , 3 months later I got my general on the 2nd try , it`s such a wonderfull hobby it`s so dignified ,you meet so many great hams , will I be a Tech someday probably not but I`m so happy with the privlidges I have now Go for It Allen ,you can allways learn CW later on down the road , besides you dont get to hear those warm friendly voices in the dits and dahs now do you 73`s N1JTZ

> Ditto! I for one get very tired of all the gabbing about this inconsequential subject. I got my licenses - Tech, General, & EXTRA - after 45 years of wanting to be a HAM now that I am retired I'm going to enjoy the hobby regardless of the opinion of some old timers who want to downgrade anyone with an Extra ticket and the lack of CW. By the way it is on my to learn list, but the more I hear of this bantering the less likely I am to want to join the exclusive club that is being professed. So please can we quit beating this poor dead horse. Sorry but I reached my limit.

20852. 2m yagi for new radio

I have cut a deal for a used 2m ssb radio; now I need to make an antenna to go with it. I don't have VHF measurement capability.

Please tell me, of all the different yagi designs out there, which is your favorite for "least-tuning-required-if-built-to-print"?

Hi All,

  I have developed an Microsoft Excel worksheet that will calculate headings and distance based on the latitude and longitude of the user's QTH.

  It is available free to all on my website (see below).

Download free of charge DXAtas from DXAtlas.com
You can calculate any distance to anywhere and see Grey Line real time,
Sunrise and sunset times etc etc.

The long path is aways 24,600 miles less the short path distance.

Ken

Brian,

When, in your lifetime, did the ham license exams "migrate down to multiple guess"????

I got my novice back in '66, my general in '67 (it was upgrade in a year or get out back then), my advanced in '69...
And, then after getting drafted, doing my military stint and raising 3 kids, some 7-8 years ago, got my extra.

Every single one of my tests were multiple guess.

I was just wondering what ham tests you took that were not the usual "multiple guess" type.

Subject: [ham-antennas] Re: "dumming down"

Brian,

When, in your lifetime, did the ham license exams "migrate down to multiple guess"????

I got my novice back in '66, my general in '67 (it was upgrade in a year or get out back then), my advanced in '69...
And, then after getting drafted, doing my military stint and raising 3 kids, some 7-8 years ago, got my extra.

Every single one of my tests were multiple guess.

I was just wondering what ham tests you took that were not the usual "multiple guess" type.

20857. Dual Beam Pro Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-27 12:17:25 UTC
From: s.melton306@btinternet.com
Topic: 20857 Message: 20857

Hi to All, I am new to the group and this is my 1st posting. I am currently gathering together the bits required to home brew a Dual Beam Pro Antenna, link pasted below. Please can anyone advise me on the contents of the Transformer/Balun unit will be or a rough guess by someone with a lot more experience than me. Currently getting stuck into SDR in a big way and really enjoying it. My setup can be seen on QRZ.com
http://www.proantennas.co.uk/dualbeampro.htm

Thank you in advance for any thoughts or knowledge gained.

Simon M6AQL

20858. Re: [ham-antennas] long path

Date: 2011-11-27 12:51:04 UTC
From: WA8JXM
Topic: 20821 Message: 20858

Just in case anyone is not aware of it, QRZ.COM provides both short and long path distances for each station along with the heading. The long path heading is, of course, the opposite direction by 180 degrees. If a station's short path heading is 60 degrees, the long path is 60+180=240 degrees.

Topic: 20821 Message: 20859

Yes, and the nice part about QRZ.com is that it is quite accurate. It uses the grid squares to compute distance.

HAM Radio's roots are buried deep in Morse code, other than: "it is more fun (but work) than
talking and has some power and distance advantages" it is of no consequence.
If we learned the "Q" and pro signals while we learned the code it can be a pretty big thrill to
talk with OMs all over the world using your new language.
Join a local HAM club that has "code classes" and learn everything that goes along with the code.

If some one doesn't want to learn cw I see no reason to make them learn it.
Unnumbered HAMS from day one never used it and promptly forgot it.

20861. Re: [ham-antennas] Dual Beam Pro Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-27 14:30:21 UTC
From: Artekmedia
Topic: 20857 Message: 20861

Simon

I have never actually seen one of these in the flesh so some of the comments that follow are purely conjectural after looking at the manufacturers literature on line

1) The name "beam" in the name is a bit misleading. The antenna is basically a shortened 40M dipole with capacitive hats for end loading.

2) The manufacturers specs are a bit vague on dimensions but playing around with the general geometry I came up with a computer model that is close dimensionally (I think) and when modeled at a height of 10 meters above average ground I get a feed point impedance of 50 ohms at 7MHz . This implies that the feed point balun is likely a standard 1:1 type balun.

3) The manufacturer claims that the antenna is only resonant at 7 MHz and that a tuner is required for the bands. The computer model confirms this and the mismatch is quite high on the other bands so I would keep my coax runs relatively short (20M or less) to minimize the coax losses due to SWR on the other bands. Either that or you will need a rather expensive remote ATU close to the antenna

4) The antenna patterns on 40M are as you would expect for any dipole the standard figure 8. Some of the other bands are quite interesting however and on 15M for example the end loadiung elements turn the antenna into quite a cloud warmer with over half of the energy going straight up :-)

If it were me I would look for something other design to emulate. Tell us more about what your goals and limitations for an antenna are and maybe the group can give you some other ideas on another approach

If the center area of the dipole is as high as you can get it, I think you are about as good as
it can get on your lot.

From: james27613
Topic: 20852 Message: 20863

hi Brian,

While not a Yagi, take a look at the Moxon for 2M,
similar performance as a two element yagi but takes up
less space and is fed with 50 Ohm coax directly.
Works great as built from the plan.

http://www.scribd.com/doc/8511822/The-Moxon-Rectangle-on-2-Meters

Works great for vertical FM or horizontal SSB use.

I've got them for 2m, 6m and 20m.

See www.cebik.com for wealth of antanna information,
you need to register, no cost, keeps out mass downloaders.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-27 17:55:13 UTC
From: Dale H. Cole K8TS
Topic: 20850 Message: 20865

Hi Folks--I started this thread, but never expected it to go as it is. All I wanted to do was bring to light, that some take to lightly the innocence and means of the new generation of amateur ops, and give them credit for what they have accomplished. Never did I expect it to go as it has. We all have great memories, and so will those who are just getting started.

That said, there is a wonderful certificate available from ARRL in there awards section that honors Elmer's. Have one sent to your favorite Elmer (s). They will take pride that they have changed the life of one individual. Chances are they will cherish it as they do their their first license. I don't remember it costing anything. Send one. Neat Xmas present for those who helped YOU make this such a great hobby.

So, as Van said, let's get back to loops, and rombics for the new cycle.

Good DX, and '73

Subject: [ham-antennas] Moderator Regarding: The "dumming down" Topic

Ok folks, some are getting tired of this
thread, as this is a Ham-Antennas Group, and the
posts should be about antenna subjects.

While this new record number of Hams is 'cause for celebration',
some posters have started denigrating others talents concerning
Ham radio code and electronics knowledge in general.
This is happening not only on this group, but several others as well.

This is not very nice, is tacky, and does NOTHING to make
others proud of being an Amateur/Ham radio operator.

The best of the comments have already been made,
(SEE the EXCELLENT comment below by KE7SBE in Arizona), and
there are others complaining of tiresome posts, so it's time
for the moderator to jump in and terminate this thread.

Please RETURN to Antenna Subjects and restore the reflector
to appropriate postings.

Thank You
Van Lincoln
moderator

Thanks again, Sigi. I should have been more clear- I like the way 4nec2 does the sweeps and 3D better than the way mmana does them. I know mmana does those things too. Unless I'm missing something (entirely possible!) mmana will not allow me to set specific start and stop frequencies for sweeps (as well as step size) and will not allow cursor readout at any point across the graph as 4nec2 does. The only thing I see in mmana for sweeps is BW choice at fixed settings. The difference in computation speed between the two programs is amazing. mmana is definitely much faster!

If you need a bw setting that is not in the list you can type them in by
hand ...

yes ... 4 additional steps in the graphics can be too low if you make a wide
sweep ... but more points would need too much time if you have a complicated
antenna with lots of elements ...
what I do is for faster calculating of those sweeps I lower accuracy a bit
(lowering the number of elements) ... and only if I need a closer look I
make exacter calculations
You have to know the limitations of the engine in the soft... but if you
learned how to use mmana it is a "rocket"

Subject: Re: [ham-antennas] Moderator Regarding: The "dumming down" Topic

Hi Folks--I started this thread, but never expected it to go as it is. All I wanted to do was bring to light, that some take to lightly the innocence and means of the new generation of amateur ops, and give them credit for what they have accomplished. Never did I expect it to go as it has. We all have great memories, and so will those who are just getting started.

That said, there is a wonderful certificate available from ARRL in there awards section that honors Elmer's. Have one sent to your favorite Elmer (s). They will take pride that they have changed the life of one individual. Chances are they will cherish it as they do their their first license. I don't remember it costing anything. Send one. Neat Xmas present for those who helped YOU make this such a great hobby.

So, as Van said, let's get back to loops, and rombics for the new cycle.

Good DX, and '73

Dale H. Cole K8TS

Subject: [ham-antennas] Moderator Regarding: The "dumming down" Topic

Ok folks, some are getting tired of this
thread, as this is a Ham-Antennas Group, and the
posts should be about antenna subjects.

While this new record number of Hams is 'cause for celebration',
some posters have started denigrating others talents concerning
Ham radio code and electronics knowledge in general.

This is happening not only on this group, but several others as well.

This is not very nice, is tacky, and does NOTHING to make
others proud of being an Amateur/Ham radio operator.

The best of the comments have already been made,
(SEE the EXCELLENT comment below by KE7SBE in Arizona), and
there are others complaining of tiresome posts, so it's time
for the moderator to jump in and terminate this thread.

Please RETURN to Antenna Subjects and restore the reflector
to appropriate postings.

Thank You
Van Lincoln
moderator

20870. Re: "dumming down"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-27 23:04:12 UTC
From: James
Topic: 20798 Message: 20870

Hi Gloria,

You are not the only one to have a "mental block" about morse code. I am now 67, and first tried learning the code in high school, and then again, off and on, over the next 40 years. There was a point in which the whole thing turned into "noise" and I couldn't tell a dit from a dot. Even with the advent of the "computer age", none of the software would able me to pass the "noise" barrier.... and I bought my first computer in 1978!

I was told to "just keep at it", "keep on pluggin'", and "you're just not working hard enough", etc, etc, ... Finally, I realized that it wasn't "me", but just that the normal methods of learning the code didn't work. So, I started to look around, read a couple of books, tried different things, and may have found a method which works... for me, at least. Apparently, everyone is not "wired" to learn code the same way.

During the Vietnam War era the US Military taught high speed code reception to code breakers using a "sound alike" method... according to a comment I found on a web page. I've found a little information on the web and am using it to give this a tryout... so far the results are encouraging. My goal is to be able to communicate with CW at 15wpm... not very lofty, but a major life accomplishment for me.

Now... to stay on topic.... my opinions as far as "dumming down" is concerned... everyone has different talents to bring to this very large table called "ham radio". Morse code is just another operating mode and we should have done away with its high speed requirement 20 years ago. If we want to restrict ham radio, lets have the test contain binary and hexadecimal math problems! That's important stuff these days. How about having test takers write a two page paper on "string theory"?

Just kidding! Ham radio is a large house with hundreds of rooms and doors. There's something interesting going on in every one of those rooms. I've found "my" rooms and am having a great time!

20871. Twin-T Vertical Dipole MMANA Model

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-27 23:11:44 UTC
From: Joe Hutchens
Topic: 20871 Message: 20871

I am modeling a Twin-T vertical dipole using MMANA-GAL Basic. Some call it a T-Bar and some call it a Sideway-H. I first modeled it with all wire elements. Then I changed the vertical element to aluminum tubing (same length) and changed the size to 12mm. I left the wire caps at .8mm. I thought the resonant frequency would drop with the change to tubing, but it goes higher. Why? That’s my first question.

This antenna is already installed and operational. I'm feeding it with 300-ohm ladder-line. How can I model the antenna with 100 feet of ladder-line? That is my second question.

The T-bars are not straight. The bottom bar is shaped like a V (about 165 deg angle) and the top is shaped like an inverted V (about 142 degree angle).

No matching is done at the feed point. I use a 1:1 current balun at the antenna tuner.

You can model it two ways ...
Model it without feeding line and use transmission line calculator to show the shack ends impedance ...
Or model it with feeding-line ...just 2 lines from feeding-point away and a short third line at shack end were the source is added ..

20879. RE: AW: [ham-antennas] Twin-T Vertical Dipole MMANA Model

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-28 17:24:09 UTC
From: Joe Hutchens
Topic: 20871 Message: 20879

I tried suggestion 2.

I opened the dipole at the center .0127m. (The old source.) I
connected a wire from each side of dipole center and ran them 30.48
meters to the shack end. At the end, I placed a short wire between the
two and placed the new source in the middle of that wire.

It didn't work, so I must have done something wrong or MMANA can't model
the feedline. Should I define a load?

From: Mark M
Topic: 20852 Message: 20885

This response may draw the ire of some. Why don't you just build a simple dipole? When it comes to antennas, I have found VHF to be much less exacting than HF. A dipole cut to the formula that is in all our books should do the job just fine and for less expense and time. Now it may be the case that you want the challenge of building a yagi - I get that and understand it's an important part of our hobby. If you want the challenge more power to you . If you just want to get on the air, a dipole or even and old tv VHF antenna will do you just fine.

Subject: RE: [ham-antennas] Re: 2m yagi for new radio

Oh, there are many, many different plans. Not owning a vhf swr meter, what I'm asking for is help narrowing my search to those designs that really don't need tuning if built "to print".

I can hold .005" tolerance easily.

Brian you should Google 2 meter yagis and you will come up with lots of different plans for a suitable beam for 2 meter SSB.

20886. RE: [ham-antennas] Re: 2m yagi for new radio

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-28 23:47:33 UTC
From: KA9EGW
Topic: 20852 Message: 20886

I have a J-pole for FM, soon to be a J-beam for FM, and a 135' OCF dipole fed with ladder line for HF.

I wish to cover almost 70 miles on 2m CW simplex with combined HAAT of about 80' and a unity-gain omni antenna at 50' at the other end. I live in a little town way out in the country in a very tall 2-story house with a very open-minded YL and I can have any antenna I want within the town's max height of 35 feet.

My best brasspounding buddy, who is disabled, I've known since '77 [we got our tickets together in '79 and all our upgrades together in '80, '80, '81 and '82, and our commercial tickets together in '83] lives in a big old apartment building in a highly congested part of the big city, pure HF-QRN hell, S9+20dB -or more- noise most of the time. Just S9 noise is a *very* quiet day there. With DSP there, CW filters in both of his IFs, and 3 audio filters on his end, we can work HF CW about half the time, armchair copy maybe 20-25%.

However, neither of us ever got around to getting a decent VHF directional wattmeter, and in this economy neither of us is likely to anytime soon...but having access to a complete machine shop I can build whatever it takes to do the job; I just need the right specs to build to and/or a good idea for a no-buck reflectometer good to 150Mc...

Or someone with a decent VHF-capable reflectometer they'll trade for a working BC-221 with book...

To tell you the truth you will need a meter no mater what you build, I would get ahold of your local club and ask if a member has one that you can use or have him/her come over to Elmer you.
I made a yagi that had bad coax and I didn't even know it till I put an analyzer, it's a good way to blow up a rig!
Also if your making a portable yagi see if you have a cb shop near you, and ask if they have an analyzer that covers 144mhz or the band your shooting for.

From: KA9EGW
Topic: 20852 Message: 20888

I had been looking at the design in W4RNL's article in the 12/04 QST, where it is direct-feed with no gamma match and supposedly 10.2dBi gain and SWR <1.5 across the entire band.

Perhaps I am addressing the problem in the wrong order...it occurs to me I *do* have access to a PCB mill after all...anyone got a .dxf or Gerber file for a decent reflectometer head?

See if you can get one of those cheap meters for cb use
Search for a small one with only one meter and only 2 inches wide
They work well up to 2m and even on 70 cm can be helpful
I changed the bad coax connectors on mine to n style and now it is working well ... ok not as good as a "bird" .... but it works!
And should work well enough to tune an antenna to resonance/swr

For the beam: just look around in the net ... there are several proven designs that are not tooo narrowbanded with just slightly lower gain
That would be the right design for you
Something like this maybe:
http://www.g0ksc.co.uk/intro-lfa.html
direct 50 ohm feed, easy to duplicate

Dg9bfc

Congratulations. When I got my General license a friend came over and put up my 3 element tri bander, and a 75/80 and 40 M inverted V fan dipole. I talked to a lot of people on those antennas.

Give thanks to our Elmer's.

From: Chris D
Topic: 20852 Message: 20897

You might consider a 2m Moxon rectangle. Broad tuning (less than 1.5:1 from 144-148), easy and cheap to build, small, and decent enough gain of 5+ dB. I built one recently and could work a repeater 20+ miles away from inside my work building with 1 watt. Had the electrical wire, 1/2" pvc, coax and connector, so the only only cost was a couple of bucks for some pvc fittings.

Brian,
You might want to consider the "Quagi" for your antenna project. It is a hybrid between a yagi and quad. Very easy to construct, somewhat forgiving in construction, high gain and simple feed system and use locally available materials. I've built several of these antennas for 2 mtrs, 1.25 fm and for 70 cm and all have worked flawlessly.

Try the ARRL Antenna Book. It's full of great construction projects that are easy to build.

From: robert
Topic: 20901 Message: 20901

I know there is a site on the internet that gives the length of coax for matching stubs. I hope some out here know where it is. I know 234 diveded into freq plus times the velocity factor

20902. AW: [ham-antennas] 75 ohmn matching stubs 6 meters

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-30 19:49:56 UTC
From: Siegfried Jackstien
Topic: 20901 Message: 20902

Just a rough guess ... one meter :-)
Quarterwave 1.5m x 0.66 = 1 m ... but velocity factor might be different
(many 75 ohms show around 0.8 with foam insulation)

20903. Build a 2m antenna using a parabolic dish....

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-11-30 21:07:55 UTC
From: fjl43
Topic: 20903 Message: 20903

I have 2 parabolic dish antennas. One is 20 inches in diameter, and the other is 32 inches in diameter.
Has anyone tried to make a 2 meter directional antenna mounted at the focal point of the dish to enhance Transmit and Receive ?
Obviously the driven element would face the dish at the focal point of the dish. How would one make THAT driven element? Would be nice to find a 2meter LNB....but likely not available.
Any thoughts..????
Gain would be quite impressive. but highly directive.
Regards to this group..

> THAT driven element?

It would be a dipole that is made to be the driven element simply by putting a reflector behind
it. (on the side away from the dish) It could simply be a metal disk or fine screen wire.

There is another major problem, a dish will only focus and give you gain unless it is more than X
number of wavelengths in diameter. I do not know that number is or if it is a constant or a function I suspect in might be on the order of 8 or 10 times.

A two meter (146,000,000. Hz) dipole is about 38" across, so obviously the dish can not focus on
very much of the dipole if it is a 20 or 32" dish. It won't work. Yes I'm sure.

It all depends on what distances you want to work. For closer in distances(e.g. 50-200 miles), a high angle of radiation helps. For medium distances, a moderate angle is better and for long distances, a low angle is best.

A quarter wave high (65' for 80 m) is good for shorter distances. A half wave high (130' on 80m or 65' on 40m) is good for medium to longer distance and poor for closer in.

Of course reaching a half wave on 160m is impossible for most of us.

A quarter wave on 80 is a half wave on 40, and a full wave height on 20.

For a 160 thru 6 meter antenna, there is no single good answer. You can find a complete answer in the Handbook or Antenna Manual.

A metal tower will have no significant effect on a horizontal antenna. Likewise, power is not an issue either.

Ken WA8JXM

20907. Inverted L Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-01 02:25:45 UTC
From: crb102463
Topic: 1887 Message: 20907

Hello Group;
Any feed back on inverted "L" for 10-40m.
The vertical section would be about 16' and the horizontal section would be 24' in lenght with the high end at about 30'. I would have a radial filed of 28 and matched with a 4to1 unun.

How would this compare to a vetical wire of about 31' similar to an s9
vetical I already have the pole

Thanks
Randy
W9RTB

From: Richard Schmuke
Topic: 20905 Message: 20908

John each band has a optimum height so installing it at the high point of the tower is the best. It might be a little low at 160 but great on 40. Because you tower will be close to the center of the dipole it won't interfere with the radiation pattern. Here is a picture of my 5 band dipole mounted on a standoff and a 2m J-Pole on top just like you are talking about. http://s1102.photobucket.com/albums/g453/KD0ZZ/?action=view?t=DSC00949.jpg

The coax length cannot be any shorter than the length from the antenna to the rig, a whole lot longer is just added loss.

Rich ,KDØZZ , ☺

The likelyhood of damage to a component is inversely proportional to the number you have available, and directly proportional to its cost.

Subject: [ham-antennas] dipole height

is there a limit as to how high off the ground a wire antenna can be and still function properly ? My opek tech folded 6-160 meter dipole came with 75 feet of coax ,is that my limit?if I extend it will it affect it`s performance I will be putting up a 60 foot tower soon and am thinking of hanging the dipole from a standoff at that height, could the towers metal construction affect the radiation pattern I dont push more than a 100 watts and will be putting the 2 meter vertical up there along with a 40 meter taktenna no hoa in my woods hehehehe Thanks N1JTZ

I have an 80 meter resonant dipole about 50' in the air with a tower supporting the center of the dipole . works great on 10 -80 with a tuner. the higher you go ... the better (of course) with height you get a lower angle of radiation (better for DX) the lower you go the more of a NVIS antenna you'll have . also the higher you go the impedance of your antenna climbs to 72 ohms - and the lower you go closer to 50 ohms you be. I feed mine with 450 ohm ladder line (tuner has a 4:1 built in) so if you are using coax , you may want to consider a balun .... 1:1 should be fine but not sure (one of the more experienced Elmers in the group will probably fill in the finer details - I am hoping) anyway give 'er a try and experiment some - find out what works best in your yard ! and when you find out , let us know ! have fun !!

The 31' straight wire will be slightly better (maybe 1db) than the inverted L on 40M ..the other bands will be more variable. better in some directions worse in others as the horizontal portion of the inverted L will come more into play as radiator on these bands.

Go back and look at the antenna software thread on here from the last two weeks then download one of the free programs recommended (I ended up preferring 4NEC2) and look at the two antennas in simulation at each frequency

20912. extended double zepp or loop comments

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-01 17:56:24 UTC
From: goldtr8@charter.net
Topic: 20912 Message: 20912

Gents,

I need to take the existing loop 160m loop down due to poor performance from being to low to the ground (eariler posts regarding my current state of affaris so we dont have to revist this).

Before I put it something up in the air again higher closer to between 25 to 40 ft (based on trees) I took the existing loop and seperated the sections, so its kinda like a large circle but now two seperate lines no longer a loop. I checked the performance and it is similar to the loop. I did this because it was just easy to do, as I wanted a data point on comparision before the wire goes down.

Anyway, before I just go and restring a loop I am wondering if I should try an extended double zep antenna. From my research it looks like each leg would be about 340 ft long which I can manage to get in the air between 25 to 40 ft in height (based on trees). However, I can not get it in a straight line. I could make it into a U shape or lazy S, for lack of a better description.

My only goal of this antenna is to try stuff that I can build myself and the comparision will always be vs. my existing alpha delta dipole at 30Ft high.

So if I can make something better than the dipole on some bands that would be great. Currently I use the dipole on all bands as it has trapps for 160 and 80 and multiple wires for the higher bands which is why I am thinking the 340 foot for each leg (assuming I have my calculations correct).

Cost is not an issue regarding this idea (I already have the wire) only the time to spend taking the existing wire down and playing with the spud gun to get it back up in the trees.

Please give me your thoughts, pro, con or otherwise.

2nd report in 2 weeks of a loo horizontal loop on 160 M not working all
that well (as compared to?) .

Before I comment on your extended zepp what are your operating goals for
this antenna Short hop rag chew, mid distance WAS or DX?

What are feeding it with , how long is the feed line run and how are you
matching it?

20915. Re: Inverted "L" question.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-01 18:21:34 UTC
From: ffuhrer@elmore.rr.com
Topic: 20915 Message: 20915

Hi All,
I first read about the inverted "L" antenna in a Department of the Army Tech Manual (Antennas and Radio Propagation, also W1FB's "Antenna Book"). It is a good compromise antenna, simple to build, portable, and used with an antenna match and "crowsfoot counterpoise" ground, usable on any H-F band. A crowsfoot counterpoise is three wires (bare or coated) ground laid about 2 to 5 feet apart terminated at the feed point end with a ground rod and either terminated at the end of each wire by ground rods, or left loose that follows the horizontal component of the antenna. From 160 meters to 10 meters, it gives good results, and adds both vertical and horizontal components to the radiated signal. It is also a good antenna for restricted space, as the vertical part shortens the horizontal space used. The crowsfoot counterpoise eliminates any poor ground conductivity problems. You can build it as a 1/4 wave, or a 3/4 wave end fed antenna. All my versions have been 3/4 wave at the lowest operating frequency (160M). I like the gain it seems to show at the higher frequencies.

I have used this antenna for over 30 years in many different locations, at home, Field Day ops, camping, hill topping, MARS use, and it has always given good results. I have shunt loaded it, delta matched it, and just end fed it tying the braid to the counterpoise, and the center conductor to the antenna. I have supported it with a tree, a push up pole, and a tower. It always works. This antenna has been used by the Armed Forces for over 70 years, and if they like it, it must be a good antenna. I like its simplicity, and the excellent results I get. You can use it without an antenna matcher if you prune it right for single band operation. The larger the conductor you use with the antenna, and counterpoise, the lower the antenna's "Q" is, and the wider the 2:1 SWR points are. The best results is with an antenna match, and 450 ohm ladder line feedline. No external balun necessary.

Build one, and have fun,
Regards,
Fred - W4FJF.

From: Dan Schaaf
Topic: 20915 Message: 20916

Wouldn't more radials make it more efficient ?

Try to think of an Inverted L as a vertical with top hat loading. On a vertical, most of the radiation is from the lower 1/3 (or so) of the antenna.
So the inverted L is a good radiator.
Base loading is lossy using a loading coil at the base.

Best Regards
Dan Schaaf

20917. Mmana-GAl vs 4NEC2 VS reality

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-01 23:01:58 UTC
From: Artekmedia
Topic: 20917 Message: 20917

OK thanks to the early postings and urging of various list memebers I downloaded both MMAN-GAL and 4NEC2 antenna modeling programs.

After a weeks of playing with both I have a slight preference for 4NEC 2 but that is not what the post is about.

I put up an inverted L for 160M at the new QTH as I have done at several locations in the past. One difference given much play in the popular literature in recent years is that a few elevated radials are better than an extensive ground screen mounted at earth level. So I this L went up with 3 radials about 10' above ground. The new antenna was much harder to tune than I am used to ...long story no longer relevant Also I found I was just not getting out like I was used to with my earlier Ground mounted L's. (could be the fact that I now live in 160M black hole called the upper mid-west...I was warned about this when moving from NH) I began modeling things to see what was going on .

I modeled the antenna using identical coordinates and dimensions in both MMana and 4nec2. The results are as follows

1) Both programs confirmed that the ground mounted antenna with a modest (20 1/8 wavelength radials) ground mounted radial system was about 2-3 dB better than the 3 elevated radial version.

2) Both programs give different results for impedance
Mman : 7.7 -j144
4Nec2: 16.9-j127

3) The measured results with my AEA CIA-HF analyzer are
28-j0

If I lengthen the radials in the computer models to around 160-170 feet (from 132) the J component finally goes to zero. I have not tried this with the real antenna yet.

Any ideas as to why the computer models are so far off? Especially the reactive part?All modeling and measurement is done at 1.825 MHz. Both programs are set for REAL GROUND

Topic: 20912 Message: 20918

HI Dave

The comparison antenna is an alpha delta trapped dipole at 30 ft in an inverted v configuration. The loop was 3 s units lower in RX and similar reports in TX.

Feed is 450 ladderline about 60 ft in length, to a 1:1 current balun to coax into the shack

Goal is to see if I can make a better antenna on lower bands than the dipole.

Basically I have the space and trees and the antenna is the most important part of the installation. So I want to see if I can do better.

Thanks
Don

HI Sigi,

My spud gun is homemade out of PVC pipe. I finished it last weekend and it is very accurate shooting over branches. I pump it with a bicycle air pump. So now I have the means to get the wire at the maximum height that my trees will allow compared to only using a ladder with my first attempt.

The spud gun shoots a pvc projectile, it is a cool unit, if I do say so myself. :-)

Please post pictures of your spud gun in the group photo section when
you get a chance. What kind of "altitude" are you able to achieve?

don,
your spud gun sounds interesting.
do you have the instructions.
I would like to make one that works like yours.
I'm sure others would be interested as well.

we all are looking for better ways of getting our antennas up or
getting them up higher.

thanks for telling us how you do it.

Hal AA2ID

HI Sigi,

My spud gun is homemade out of PVC pipe. I finished it last weekend
and
it is very accurate shooting over branches. I pump it with a bicycle
air pump. So now I have the means to get the wire at the maximum
height that my trees will allow compared to only using a ladder with my
first attempt.

The spud gun shoots a pvc projectile, it is a cool unit, if I do say so
myself. :-)

20923. Unwanted A4 resonance shift

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-02 06:34:00 UTC
From: nelson w
Topic: 20923 Message: 20923

For some months I have had an erratic SWR with my A4. I just ran a new coax feed and now have a different problem. On all four bands (I have the 40 meter add-on) the lowest SWR is higher in frequency than the top end of the bands. All I did now was connect the new coax and not change anything else. I have been using the antenna for a number of years and have always had good SWR's at the wanted frequencies prior to the intermittent SWR problem. The only thing that I can think of that could cause this situation is a change in element length but I can't see how that could happen. I can't figure how a new length of coax could cause this problem but clearly something has changed the resonances. It looks like I'll have to disconnect the coax at the antenna and check resonances at the feedpoint of the antenna. My tower is a tilt over and I need a calm day to tilt it and those days are not very frequent. I'd like to a good idea what to look for when I do have access to the antenna. Any thoughts?

Nelson, K8DJC

What are the settings in dm1 and dm2 in mmana??
As higher you go with that numbers the more elements are calculated ... and
if that number is tooo low then the result is "bulls..." :-)
The engine in the soft can not handle wires close to ground very accurate
And next thing is that if you have

Ways to go high up the trees.

Interesting : http://www.youtube.com/watch?v=qXeXHrGaESA

And also, look at the very last picture on this page (hi) :
http://militaryradio.com/spyradio/grc109.html

I know an Austrian OM who makes huge loops using helium balloons to hang his wires at the very top of his trees.

Uups ... email went out accidently :-)
Ok ...
The engine can not handle low wires (close to ground) very accurate
Next thing is ... you wrote you have 3 elevated radials?
Not easy to have the same current in all the 3 legs ... I would increase the number .... did you measure current in the radials? I am guessing that they are not the same!!! ...
If the currents are not the same the result is that the soft also calculates radiation from the elevated radials as nvis radiation ...
What you are looking for is low angle dx ... right?!?
So you have to have equal currents in the radials that they cancel each other in radiation and only the radiation from the vertical is left ...
Problem here is that you have an inverted l and not a straight vertical ...
You will have un-equal currents regardless what you do ... and so the radials will radiate half of your power straight up
With a ground mounted inverted l it is a bit different ... there the only part that is radiating nvis is the horizontal part ...
But most of your power is transmitted from the vertical radiator
If you would make the horizontal part to 2 sides with equal length then only the vertical part would radiate cause the horizontal radiation of the now 2 tophat legs would cancel the radiation from the other side (if you have equal currents in both tophat wires)...

Increase dm1 and dm2 for better accuracy!!

Thanks for the insight about the L and the unequal radial currents, once i read that that it was so obvious. I had already increased the number of segments in both MMAna and 4NEC2 since computer power and memory are no longer a limitation

In hind site the "T" version would be a much better choice getting rid of the high angle radiation and while I have not measured any actual radial currents getting things balanced in a wooded environment would seem to be a challenge at best.

It is too late to do much more outside this year as we already have snow cover and the temperature at the moment is -12C. It is no longer any fun to "play" outside ..things to plan for next spring

One last question...You noted that Mmana is not accurate for horizontal wires near ground ...does 4NEC2 suffer the same limitation

Thanks again

Dave

Topic: 20923 Message: 20929

Probably the antenna itself is not matched and the old coax was part of the tuned circuit. When you replaced the coax, you changed the tuning.

Nelson

I had two A4's over the last 30 years (sold my last one about 10 years ago) neither had a 40M add on kit however.

The first thing I would do is reconnect the old coax and see if the problem reverts back to its original state or not.

The one problem I had over the years was with wasps and spiders building nests inside the traps which will result in the erratic SWR you were seeing to begin with. The problem can compound itself if you are running high power as the unwanted guests get carbonized and create carbon paths ruining the trap completely beyond simple cleaning and repair. I had one trap catch fire and melt . In the end I solved my problem by gluing small squares of screen wire over the 3 weep holes on the bottom side of all the traps.

The traps themselves are not that hard to disassemble and remove the outer cover from for cleaning and inspection

Good luck
Dave

20931. G5RV vs dipole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-02 15:06:07 UTC
From: wa7dxz@aol.com
Topic: 20931 Message: 20931

Here is my situation.

I need an antenna to work MARS, basically 75 meters, and sometimes 40 meters.

I have already a 30 meter dipole, and a ten meter dipole, both of which work great.

I have been using a G5RV because it was shorter... 102 ft i could fit in my yard,,, more than that, I couldnt. And, I liked using coax into the shack, I can use it with my LDG auto tuner.

The G5RV doesn't work on 10 as well as my dipole, I guess that is expected. And, it doesn't like to tune up on 30 meters,,, takes a lot of tuning to get an acceptable match.

Would I be better off to go with a 102 foot doublet/dipole (lets not start that argument again) fed with twin lead or ladderline, and run it thru my "big" manual tuner? Tune it manually, ,,, would it perform better on "all bands" than the G5RV?

Also,,, the G5RV has something like 30 feet of 300 ohm lead coming from the top of it,,, I have a good length of 450 ohm line... can I simply tie my 450 line to the 300 ohm line, and run it into the shackj? Will there be any degradation mixing the two impedances,,, remember, Im going to go through a tuner anyway.

Many thanks,,,I want max performance with the antenna on 75, and 40 and maybe 30,,, I am rarely on the other bands. I could use the dipole on 75/40 with one rig, and run 10 and 30 with the separate tuned/resonant dipoles, on another rig.

Is it worth it, will I gain anything, by going to a 102 foot dipole rather than the G5RV, and can I mix the two impedance of lead in...

Dan,
Are you more interested in making a working antenna more complicated, or using a design that WORKS? I've experimented with this antenna for over thirty years, and found that the original design is the best design. Put one up yourself, forget the antenna modeling software, and use it. See what the actual results are compared with a standard dipole cut for 160M, and at the same height. I was taught by the old school Elmer's of the 70's, no computers or antenna software back then, just cut and try. Antenna software is fine to begin the process with these days, but only by actually doing it is the proof. Just because part of the antenna is vertical doesn't mean that you have to cover your property with 200' or so of multiple ground radials. Besides, the exorbitant cost of copper or aluminum wire needed, multiple ground wires are a pesky problem when doing yard work. I once had to unwind about 100' of aluminum wire from my rider lawnmower after catching part of a 64 radial ground system (a real pain, besides the loss of a single ground wire that made absolutely no difference at the receiving station). After a point, you can only realize a minor improvement (if any) in received signal strength at the receiving station while using more than 24 ground radials under a vertical antenna. What does an eighth or a quarter of an "S" unit bring you? Not Much. The only thing that really matters is if I can hear you, and you can hear me. Forget the massive signal reports!

For those of you that have restricted space problems, the inverted "L" may be the only cost effective solution to get on "top band" or on 80M. Don't talk it to death, just get out and do it. Also, use a product like Oxyguard (available at most hardware stores, and electrical supply houses) to eliminate the chance of galvanic action between copper weld wire, copper, or aluminum connections. It will save you a big headache down the road when a bare wire combo goes bad. Works real good when you use a PL-259 on RG-6's foil and 40% aluminum braid shield wire. I haven't bought a wire dipole "off the shelf" in my whole time as an Amateur, as I build them with my own two hands. Get your antenna experience by doing it yourself.

The real pleasure is when I make good contacts off an antenna I home made myself (and saved a whole bunch of money doing it). At a recent Hamfest, I bought a box of 18 12" E.F. Johnson porcelain insulators for $10 - how can antenna building get any cheaper?
Regards,
Fred - W4FJF.

Topic: 20931 Message: 20933

Bob,

I don't know if this helps or not, but I have a 102-ft doublet like you're talking about. The only difference between it and a G5RV is that it has 100 ft of 450-ohm ladder line as a feed line which goes to a 9:1 balun and then the tuner, instead of 32 ft of ladder line and directly to the coax. (The tuner is the MFJ-998 1.5 KW autotuner, and there is only about three feet of coax between it and the rig, so losses aren't a problem.) It loads up fine on all bands from 80 to 6 except 15, which has a few "sweet spots" in the band where it will work. (As discussed in another thread, the SWR varies when it rains, so I'm going to try Scotch Guard on the feed line the next time I bring it down.) As an antenna, it works best on 20, but it's OK on the other bands. I load it up on 160 by tying the near ends of the ladder line together and using it as a T working against a set of ground radials.

The G5RV uses the ladder line as part of the antenna, so the pattern is difficult to predict. I would recommend using the 102-ft doublet with 450-ohm ladder line, a 9:1 balun (or you could try 4:1 - I found they both worked on the CW sub-bands the same), and your tuner. The SWR varies a great deal over each band (especially higher bands), but the tuner seems to take care of it, so MARS frequencies shouldn't be a problem

Fred,

You are right, it is too easy to get caught up in the theory and forget that a lot can be accomplished with less than "perfect" antenna systems.

W0BTU has a very informative web page
http://w0btu.com/Optimum_number_of_ground_radials_vs_radial_length.html
Where he shows the difference between a perfect ground radial system and a much more simple approach. The difference in 1.6 wavelengths of buried radials vs 12 wavelengths is only 2 db, only a fraction of the typical QSB fade!

According to his webpage, going from 60 radials each 0.2 wavelength to 24 radials 0.125 wavelength only loses one db. It takes four times as much wire to gain just one db!

Even if you cut the 1.6 wavelengths in half, how much would one lose? Would it be noticeable for the typical QSO? Probably not. It is easy to obsess on the theory and miss the fun.

Yes, I recommend the balun, although you might get by without it. The impedance of the doublet is fairly high across most ham bands, and the balun facilitates tuning. If you use a balanced tuner like the MFJ-976 or the old Johnson Matchbox, you wouldn't need the balun. The balun also helps eliminate RF in the shack. Frank

Fred
I did not say that your antenna does not work. I just suggested making it more efficient. Sure, you can make contacts with just about anything and say that it works great until you improve it and then say " this works FANTASTIC NOW ".
This has nothing to do with modelling on a PC. It is proven that more than 3 or 4 radials make a vertical more efficient. What was a good antenna for the military had to do with their mission. If they have a specific distance in mind, then what they develop satisfies that mission. If, however, you want tp work Austrailia from your QTH on a regular basis, you need to make it more efficient.
You can buy a roll of copper wire for peanuts. 30 radials @ 30 ft each is 900 ft and that is not expensive.
If the wires are stapled to the ground using garden staples, after one season, the wires are totally covered from grass clippings.
Look, I have a 5 band low band vertical in the middle of my yard and plenty of radials and never did 1 radial get cut by my tractor.
As I said earlier, an inveted L is a vertical and the horizontal wire at the top is top loading. Read ON4UN's Low band DXing book if you do not believe me. He is one of the leading authorities on low band antennas.
My antenna is home brew. Here it is http://k3zxl.com/Tower_Vertical/
And this antenna has worked teh world on all 5 bands , don't ask me what it cost.
An 1/8 or 1/4 S Unit means nothing if you are making QSOs across the USA. But when the QRN is high, every bit of S unit matters when you are DXing. And real DXing on 160 really requires a separate low noise receive antenna.
An S9 signal in S9+10 noise is really hard to copy.
An S2 signal in S9 noise is impossible to copy.
From reading your bio on QRZ.com, it appears that you are a rag chewer and do not quickly fall into the DXer catagory. In which case your inefficient vertical will do just fine.

I once had to unwind about 100' of aluminum wire from my rider lawnmower after catching part of a 64 radial ground system (a real pain, besides the loss of a single ground wire that made absolutely no difference at the receiving station). After a point, you can only realize a minor improvement (if any) in received signal strength at the receiving station while using more than 24 ground radials under a vertical antenna. What does an eighth or a quarter of an "S" unit bring you? Not Much. The only thing that really matters is if I can hear you, and you can hear me. Forget the massive signal reports!

For those of you that have restricted space problems, the inverted "L" may be the only cost effective solution to get on "top band" or on 80M. Don't talk it to death, just get out and do it. Also, use a product like Oxyguard (available at most hardware stores, and electrical supply houses) to eliminate the chance of galvanic action between copper weld wire, copper, or aluminum connections. It will save you a big headache down the road when a bare wire combo goes bad. Works real good when you use a PL-259 on RG-6's foil and 40% aluminum braid shield wire. I haven't bought a wire dipole "off the shelf" in my whole time as an Amateur, as I build them with my own two hands. Get your antenna experience by doing it yourself.

The real pleasure is when I make good contacts off an antenna I home made myself (and saved a whole bunch of money doing it). At a recent Hamfest, I bought a box of 18 12" E.F. Johnson porcelain insulators for $10 - how can antenna building get any cheaper?
Regards,
Fred - W4FJF.

Try QST March 2009 page 67

I built one of these and I can achieve 150 ' + - fairly accurate but if at first you don't succeed take the projectile off , reel the line back in , and try it again - leaving the projectile on the line reeling it through the limbs and leaves , it will get hung up for sure !

Topic: 1887 Message: 20939

I have been using an inverted L as my main antenna for about four years. It goes 30' vertical and about 100' horizontal. I use a counterpoise rather than ground radials. It is 2 - 3 S units better than a 80 m dipole (open wire fed) at the same height.

It tunes 160 - 6 meters. I have worked New Zealand on CW on 40 meters - I couldn't even hear the signal on my dipole which favors that direction - it is not high enough to be much more than an NVIS at 80 & 40. I have feeding it at the base with an ICOM AH-4 and using a tuner at the rig. Could not tell the difference.

The vertical portion puts out more a low angle signal than the horizontal antenna. My yard is small, so it looks like a "U" when viewed from above. The counterpoise is 3 - 4 feet above the ground and is directly under the horizontal high portion of the antenna.

Just give it a shot. It is not a Yagi, but for me, it works better than the horizontal antennas that I have tried at the current QTH.

20940. Spud Guns

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-02 23:26:20 UTC
From: James
Topic: 20912 Message: 20940

Thoughts on spud gun use for launching antenna lines;

First, I've five operational spud guns and "host" an annual 4th of July contest for the "family and friends" at my home. Over the years, we've developed different types and preferences.

1) Aquanet using a piezo igniter design is common on the internet. The electric spark ignites the hair spray and forces the potato section out of the barrel at high velocity. Unfortunately it also has blow back through the ignitor and will eventually foul it... an unreliable mechanism. Electronic ignition can also be used, however it doesn't overcome the mixture problem.

2) Works ok with propane or map gas, but the mixture is hard to control consistently... unreliable.

3) Spud gun chamber can be pressurized with air through a Schrader via a bicycle pump. Trigger mechanism is a valve normally used for lawn sprinklers.. these are pretty cheap and can be actuated by hand or electric. Pumping up the chamber to 100lbs pressure with a bicycle pump will have you cursing if you miss your target! This is my favorite type of spud gun and my air compressor is used for the contest... all fun with little work.

4) A misadventure with a spud gun will put you into the hospital or worse. I've seen a potato go through one half inch plywood. We shoot using firearm safety rules.

5) Recommended type... the gun with using a Schrader valve, but you need a good air pump if operating away from home without an electric air compresssor.

6) What do I use to launch an antenna line... slingshot. Fires every time, very little maintenance needed. Paint the sinkers yellow, make sure the line is played out or the bale is open on the spinning reel. When hoisting, you'll have 3 lines... light monofilament tied to surveyor string, tied to the main support line. No fuss, no muss, no misfires or sore muscles.

For the ground wires (or close to ground) ... as fas as I know 4nec2 uses
the same eng9ine internally ... so limitations should be the same
No wires in sharp angles (or use high numbers in dm1 and dm2 is a must!)
No wires close to ground ... yes elevated radial do work ... but not toooo
close to ground!

Topic: 20943 Message: 20943

Gents,

The below link is the inspiration for my spud gun. Mine is very similar to this design. The reason that mine is slightly different is that I started with some PVC that was laying around, plus something that was given to me. After I saw this link and watched the video, I built it and I am amazed on what 15 psi of air pressure can do from a bicycle pump. If you go higher, well don't be suprized. Also remember the pressure rating of the PVC when you pump it up.

http://www.joplin-arc.org/pages/antennalauncher.html

Now any comments on my zepp antenna idea? :-)

HI Sigi,

My spud gun is homemade out of PVC pipe. I finished it last weekend and

it is very accurate shooting over branches. I pump it with a bicycle
air pump. So now I have the means to get the wire at the maximum
height that my trees will allow compared to only using a ladder with my
first attempt.

The spud gun shoots a pvc projectile, it is a cool unit, if I do say so
myself. :-)

Dave,
Thank you for taking the time and effort to research and model and your views are respectfully noted. The actual measurements are 5 metres long with the end hats at 2.5 metres each.

As an M6 licence holder I am restriced to 10 watts, but usually use only 5 watts. I have a home made tower on the side of my garage that can get up to about 12 m high realistically and this has a Clansman centre balun straight through fed with about 15m of military coax and can get about 15 m of wire out from either side to each end of the garden. I am using a Flexradio 3000 with the internal Tuner.

My hopes are to build a better antenna to use on as many of the bands as possible and have also looked a home building a Cobweb. I also plan to sit the Intermediate stage exam within the next month, allowing the use of 50 watts, but again im just as happy using the 5 watts on my Flexradio 1500 with the LDG ZPro 2 with WSPR etc with 12m of wire in an inverted V with 1:1 balun like the following with quite good results.
http://www.iv3sbe.webfundis.net/html/Rybakov806.htm I know im never going to get 1 antenna to cover everything, but would like to use as much of the HF bands as possible.

Thanks again for your time and patience 73 Simon M6AQL

20945. FW: Re: [ham-antennas] extended double zepp or loop comments

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-04 00:32:39 UTC
From: goldtr8@charter.net
Topic: 20945 Message: 20945

Well the spud gun worked awsome and I almost have the antenna finished.
Neighbors and wife both think I am nuts.

I have the antenna as two seperate wires right now with the middle
section high and ends both low at about 250 ft per leg. Its in a u
shape waiting to be finished tomorrow.

All signals below are in comparision with my aplha delta trapped dipole
at 35 ft.

So far just playing 160m nothing to compare with as no good signals
80m the wire is 2 to 3 s units
40 m its about 1 s unit less
20 m its about a wash
17 m its about 3 s units higher
15 m its about 2 s units higher
12 m its about the same
10 m its about 2 units lower.

The ends are real low right now but the rest of the antenna is between
30 to 40 ft high. I will be finishing tomorrow with the last 50 ft
section and tie the ends togehter. I guess I have decided that I want
the loop now.

20946. Re: G5RV vs dipole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-04 00:36:31 UTC
From: kd8dvy@ymail.com
Topic: 20931 Message: 20946

I have worked with both types of antennas but the one I love the best is the Doublet dipole. The thing about the doublet is that it needs to be 125-135'. The length does not have to be accurate. The room that your 102' G5RV is in is a good place to put up the doublet. What I mean is that you can bend the ends down as long as your end support is not metal.

Mine is 135' across the top along with 135' inverted V. So it is in a fan dipole configuration. The ladder line is about 100' +/- where it runs into the shack where it terminates into a 4:1 balun with a piece of coax that is about 3' long.

If you want to use your manual tuner that will work that is how I was set-up. I found that the doublet has high ohms and high swr but efficiency is 90-95%, so what ever tuner you use make sure that you have some kind of balun (4;1, 6;1, 9;1).

You should hear my QRP signal. I operate 10W (PEP) on SSB and 25W on PSK31.

Just get the antenna as high as you can. Try this website if it is not a link just copy and paste.

http://www.hamuniverse.com/hfdoublet.html

Harold/KD8DVY
SSB QRP is the bestest

20947. Re: Inverted "L" Antenna Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-04 12:02:23 UTC
From: ffuhrer@elmore.rr.com
Topic: 20947 Message: 20947

Dan,
Can you really tell actually how efficient your inverted "L" antenna is? All the measurements in the world of Amateur Radio is based on "Relative SWR". Relative to what? Relative to so many variables that are too many to list here. That isotropic antenna based on a theory? A wire hung in free space that has no other effects on it? The isotropic antenna is definitely not a practical reference to measure your ground based antenna against. I never trust any gain measurements compared against an imaginary "ideal" antenna (as in DBI). And I approach any antenna based on the compared dipole earth based antenna with caution, as no Amateur antenna has a clear flat field with no obstructions within the measured area (which could be square miles in area). We all have obstructions we deal with daily that change constantly, from power poles, portable buildings, the number of cars in the yard to alkaline or acidic soil. Do you know exactly what your ground conductivity is from one day to the next? Is your ground based on ground level, or at the actual water table that changes constantly? From the morning dew on your roof and yard to the daytime dry conditions, so many variables that constantly change? The definitive book on antennas and radio propagation has never been printed, and probably never will. Haven't you seen your Relative SWR meter change from day to day, and time of each day? Nothing is constant.

When I tune an antenna, I never use SWR as an actual indication of its performance. I use reflected power as an indication of efficiency, as it is a much more accurate way of measuring antenna performance. I also use a field strength meter, and a compass to get an idea of what the antenna pattern really is. That is, if I really get curious about a new antenna I am trying out.

I used to be a big DX fiend, but when my job got me to moving around so much I gave the venerable DXCC Award up, as my moves were always more than 75 miles or more - therefore negating the QSL cards I collected for that award. Yet, I've probably had more DX contacts than you have (or at least equal to) over the more than thirty years I've been a Ham. Now that I've retired, I have a house on top a hill of iron bearing clay that gives me a better ground that I ever have had in all my life. I could put up a random length wire, and still have one of the strongest signals barefoot in the group I'm talking to at the time. This is no boast, its fact. Some ask what kind of Linear I'm running when I'm running a barefoot 80W. All my antennas are at 60', except a few NVIS antennas I use for Navy MARS (because of the rolloff this hill causes to the low incidence angle to the horizon).

I may enjoy ragchewing, but my "ragchewing" isn't limited to the CONUS, its worldwide. I am not a "contestor", because what do you learn by just exchanging call signs, contact number and signal strength? How do you make friends worldwide by that?

One last comment, have you priced antenna wire from the Wireman lately? It's not cheap at all when you are getting hundreds of feet at a time. Even common house wire has tripled since five years ago. Why are contractors using PVC pipe, rather than copper pipe lately? Copper flashing that once was normally used on roofs are now replaced by UV stabilized plastic sheeting 15 mils thick. Copper anything is not "cheap" anymore.

I've looked at antenna theory in the ARRL Antenna Book, understand it, but end up doing it my way. Book learning is fine, it gives you a point to start from, but practical experience beats it out any day. I'm not criticizing you in any way, but poking holes in what is generally accepted as THE Antenna Theory of today. In my considered opinion, the ARRL Antenna Book may be entirely correct at frequencies above VHF, but on H-F, MW, VLF, and low VHF it is just a good guideline to start from.

Best Regards,
Fred - W4FJF.

Reflected power has nothing to do with antenna performance. The only place where it shows efficiency is if you are using lossy feedline.

Take, for example, a center fed full wave antenna ("Two Half Waves in Phase") such as an 80m dipole fed with open wire on 40 or 20m. The SWR will be high, the reflected power will be high, but that reflected power goes right back up the feedline (assuming low loss open wire) and does not effect efficiency. In fact the Two Half Waves in Phase is a very efficient antenna as long as you have a tuner feeding the feedline.

Same thing for a Double Extended Zepp, high reflected power if you can measure it, but it goes right back to the antenna and has good performance.

Reflected power is NOT lost power unless you have lossy feedline.

Fred
The cost of wire :
It depends on what you want to achieve. If you want efficiency on a vertical antenna and Inverted L included, you have to buy radial wire. So you pay maybe $50 for a roll of wire. Big Deal ! It makes the antenna efficient which means you are not throwing wasted power into the ground or the coax.

While SWR is a measure of ratio of reflected power to forward power (Or Antenna Z to Coax Z), it is not an indicator of antenna efficiency. You can have a 1:1 SWR with one radial and an SWR of 1:1 with 100 radials. It has nothing to do with antenna efficiency. It has everything to do with the feedpoint impedance relative to the coax impedance.
You can read about it here http://en.wikipedia.org/wiki/Antenna_efficiency

A Vertical antenna feedpoint impedance with sufficient radials is 37 ohms. This can be measured with an MFJ-259B. SWR is :
50 ohms / Antenna Z. So, if antenna Z is 37 ohms (Ideal) then SWR is 1.35:1 at the resonant frequency of the antenna.

Now, if radials are few The Antenna Z is not 37 ohms and so the SWR is not 1.35:1 but higher. Now, you can fool yourself into thinking that the antenna is OK by trimming the antenna or adding to the antenna to get the SWR to your liking, but it is still ineffient. All you will have done is make the SWR meter think that the antenna is OK.

All of the practical experience means nothing if it does not agree with the math for making an efficient antenna.

I know, a lot of Old Timers seem very inclined to fall back on what they may have learned or thought from many years ago. And much of that info is still valid. I am an Old timer (63 years old and licensed in 1963) but I am not closed minded to up to date information on any subject, antennas included. A lot of work has been done over the years and it should not be ignored.

The nice thing about Antenna Modelling is that it does a great job of predicting how an antenna will perform before you start cutting wire or expensive aluminum tubing.

The ARRL antenna book and the ON4UN Low band DXing Book are the standards and a lot of practiical and theoretical work has gone into them. I have military manuals on antenna design and construction and the information is not different from the two books I just mentioned. In fact much of the modelling software originated for use by the military. Modelling will even tell you teh effect of other structures near the antenna under construction. That is not something you can figure out by practical experience. The model will tell you how the radiation pattern is affected by a nearby tower or some other metal structure.

I think it would be wise to keep an open mind on things . I have a friend who says “ If it was good enough for my grandfather, then it’s good enough for me “ and that makes my hair stand on end. He is as closed mnded and conservative as a person can get.

Subject: [ham-antennas] Spud Guns

Thoughts on spud gun use for launching antenna lines;

First, I've five operational spud guns and "host" an annual 4th of July contest for the "family and friends" at my home. Over the years, we've developed different types and preferences.

1) Aquanet using a piezo igniter design is common on the internet. The electric spark ignites the hair spray and forces the potato section out of the barrel at high velocity. Unfortunately it also has blow back through the ignitor and will eventually foul it... an unreliable mechanism. Electronic ignition can also be used, however it doesn't overcome the mixture problem.

2) Works ok with propane or map gas, but the mixture is hard to control consistently... unreliable.

3) Spud gun chamber can be pressurized with air through a Schrader via a bicycle pump. Trigger mechanism is a valve normally used for lawn sprinklers.. these are pretty cheap and can be actuated by hand or electric. Pumping up the chamber to 100lbs pressure with a bicycle pump will have you cursing if you miss your target! This is my favorite type of spud gun and my air compressor is used for the contest... all fun with little work.

4) A misadventure with a spud gun will put you into the hospital or worse. I've seen a potato go through one half inch plywood. We shoot using firearm safety rules.

5) Recommended type... the gun with using a Schrader valve, but you need a good air pump if operating away from home without an electric air compresssor.

6) What do I use to launch an antenna line... slingshot. Fires every time, very little maintenance needed. Paint the sinkers yellow, make sure the line is played out or the bale is open on the spinning reel. When hoisting, you'll have 3 lines... light monofilament tied to surveyor string, tied to the main support line. No fuss, no muss, no misfires or sore

muscles.

I used weed trimmer line as it is light and very thick. I did this to not have problems pulling the wire up thru the trees. Right now there are no leaves in the trees so it is fairly easy to pull thru.

One thing to remember if you determine that you do not like where the line went and are going to do a second shot remove your projectile from the line. It can get caught in branches and then you can not get it back down.

Also do not stand on your line when shooting as it makes a short shot.

At 40 PSI you can shoot high and far, so be safe.

Antenna is almost done and final form will be a loop.

As long as the line is truly "balanced" there should be little or no
radiation in the shack

Dave,
how can I ensure that it is "balanced".
Thanks for your reply.

This is just a option . I happen to also fish so I use a bass rod to launch a heavy weight over the trees. It might not work with a light weight Zebco reel and line but I use a stiff rod and a Abu Garcia baitcast reel with 50Lb test spider wire. It works good and was already here.

I used weed trimmer line as it is light and very thick. I did this to not have problems pulling the wire up thru the trees. Right now there are no leaves in the trees so it is fairly easy to pull thru.

One thing to remember if you determine that you do not like where the line went and are going to do a second shot remove your projectile from the line. It can get caught in branches and then you can not get it back down.

Also do not stand on your line when shooting as it makes a short shot.

At 40 PSI you can shoot high and far, so be safe.

Antenna is almost done and final form will be a loop.

I've had good luck with the old slingshot myself.

I use the a 1oz egg sinker and red mono line so I can see it easier too. Depending on the tree sometimes it's difficult to get the line to drop within reach so spring or late fall is the best time to get this lines in the trees.

Good info the spudguns. I havent tried other forms of ignition...interesting.

Subject: [ham-antennas] Spud Guns

Thoughts on spud gun use for launching antenna lines;

First, I've five operational spud guns and "host" an annual 4th of July contest for the "family and friends" at my home. Over the years, we've developed different types and preferences.

1) Aquanet using a piezo igniter design is common on the internet. The electric spark ignites the hair spray and forces the potato section out of the barrel at high velocity. Unfortunately it also has blow back through the ignitor and will eventually foul it... an unreliable mechanism. Electronic ignition can also be used, however it doesn't overcome the mixture problem.

2) Works ok with propane or map gas, but the mixture is hard to control consistently... unreliable.

3) Spud gun chamber can be pressurized with air through a Schrader via a bicycle pump. Trigger mechanism is a valve normally used for lawn sprinklers.. these are pretty cheap and can be actuated by hand or electric. Pumping up the chamber to 100lbs pressure with a bicycle pump will have you cursing if you miss your target! This is my favorite type of spud gun and my air compressor is used for the contest... all fun with little work.

4) A misadventure with a spud gun will put you into the hospital or worse. I've seen a potato go through one half inch plywood. We shoot using firearm safety rules.

5) Recommended type... the gun with using a Schrader valve, but you need a good air pump if operating away from home without an electric air compresssor.

6) What do I use to launch an antenna line... slingshot. Fires every time, very little maintenance needed. Paint the sinkers yellow, make sure the line is played out or the bale is open on the spinning reel. When hoisting, you'll have 3 lines... light monofilament tied to surveyor string, tied to the main support line. No fuss, no muss, no misfires or sore muscles.

From: Richard Schmuke
Topic: 20952 Message: 20959

I have no problem with my doublet and as long as you have a balanced type antenna you should not have any RF problems with ladderline. I did have a little snag with my MFJ 962D tuner, it did not go down to 1:1 easily on all bands. So I made my own current balun and run about a foot of coax to my tuner. I also made my balun switchable from as a 1:1 or a 4:1, different bands worked better with one or the other. My balun is inside the shack by the way. You can get into changing ladderline length but the can get complex.

Have a doublet and fed with 450 ladderline and trying to feed it into the shack. Ordered a couple of bulkheads from The Wireman to run this ladderline in. Will this ladderline radiate in my shack? Am I better off using a 4:1 balun on the outside and running coax to the inside?

8' surf rod with an ancient Penn spinning reel (flea market special) ,
40 lb spider wire and 2 or 3 oz "bank sinkers". lighter than 2 oz wont
always pull the spider wire to the ground. heavier than 3oz is hard to
control for casting accuracy. easily good to 80'. Not where you wanted
it ? never and I mean never pull the sinker back through the tree 75% of
the time it gets caught. I tie a piece of pink florescent plant tie to
the bank sinker so I can see it better in the woods. Once over the tree
I pull parachute cord back through the tree with the spider wire then
use the parachute cord to pull heavy rope.

I find the idea of the spud gun for accuracy appealing maybe I'll put it
on my Xmas wish list some year . As one poster noted earlier there is
the potential for spud gun explosive accidents if not used properly.
Surf casting rods never explode but as noted above the unintended
consequence of trying to pull a fouled bank sinker from a tree can
result in a bank sinker coming back at you out of the tree at amazing
speed , fortunately I was wearing a hard hat ...now I never try to pull
sinkers back through only lines :-)

You cant (easily) but in general keep it away (6" or more) from other objects especially metal objects..... generally not a problem.

You will know if you start getting RF burns or the florescent lights get brighter when you transmit if you have RF in the shack :-)

I'll stick to my Bow and arrow. I use a fiberglass heavy "Arrow"
(electric fence post 1.4" diameter) some small nylon line.

Good shot and line is placed within inches of desired location.

no possible explosive injuries either

20963. Re: Inverted "L" Antenna Question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-04 17:32:32 UTC
From: fred
Topic: 20947 Message: 20963

three years ago I had to replace the copper dipole and had sticker shock when I saw the price . looked at the 1/16 " galvanize lift cable and at 10 cents per foot I tried it . with 102 feet of wire and clamps it was about 12.00 dollars for everything . put it up the next day and am still using it with no problems . another bonus , if you live in an area with antenna gestapo it is almost invisible after it has been up for awhile . it turns a dull grey colour . don't use end insulators and hide the centre insulator and 450 ohm line in a tree .
had mine in the back yard and no one ever noticed it .
kd5pnt

--- In ham-antennas@yahoogroups.com, <ffuhrer@...> wrote:
>
> Dan,
> Can you really tell actually how efficient your inverted "L" antenna is? All the measurements in the world of Amateur Radio is based on "Relative SWR". Relative to what? Relative to so many variables that are too many to list here. That isotropic antenna based on a theory? A wire hung in free space that has no other effects on it? The isotropic antenna is definitely not a practical reference to measure your ground based antenna against. I never trust any gain measurements compared against an imaginary "ideal" antenna (as in DBI). And I approach any antenna based on the compared dipole earth based antenna with caution, as no Amateur antenna has a clear flat field with no obstructions within the measured area (which could be square miles in area). We all have obstructions we deal with daily that change constantly, from power poles, portable buildings, the number of cars in the yard to alkaline or acidic soil. Do you know exactly what your ground conductivity is from one day to the next? Is your ground based on ground level, or at the actual water table that changes constantly? From the morning dew on your roof and yard to the daytime dry conditions, so many variables that constantly change? The definitive book on antennas and radio propagation has never been printed, and probably never will. Haven't you seen your Relative SWR meter change from day to day, and time of each day? Nothing is constant.
>
> When I tune an antenna, I never use SWR as an actual indication of its performance. I use reflected power as an indication of efficiency, as it is a much more accurate way of measuring antenna performance. I also use a field strength meter, and a compass to get an idea of what the antenna pattern really is. That is, if I really get curious about a new antenna I am trying out.
>
> I used to be a big DX fiend, but when my job got me to moving around so much I gave the venerable DXCC Award up, as my moves were always more than 75 miles or more - therefore negating the QSL cards I collected for that award. Yet, I've probably had more DX contacts than you have (or at least equal to) over the more than thirty years I've been a Ham. Now that I've retired, I have a house on top a hill of iron bearing clay that gives me a better ground that I ever have had in all my life. I could put up a random length wire, and still have one of the strongest signals barefoot in the group I'm talking to at the time. This is no boast, its fact. Some ask what kind of Linear I'm running when I'm running a barefoot 80W. All my antennas are at 60', except a few NVIS antennas I use for Navy MARS (because of

the rolloff this hill causes to the low incidence angle to the horizon).
>
> I may enjoy ragchewing, but my "ragchewing" isn't limited to the CONUS, its worldwide. I am not a "contestor", because what do you learn by just exchanging call signs, contact number and signal strength? How do you make friends worldwide by that?
>
> One last comment, have you priced antenna wire from the Wireman lately? It's not cheap at all when you are getting hundreds of feet at a time. Even common house wire has tripled since five years ago. Why are contractors using PVC pipe, rather than copper pipe lately? Copper flashing that once was normally used on roofs are now replaced by UV stabilized plastic sheeting 15 mils thick. Copper anything is not "cheap" anymore.
>
> I've looked at antenna theory in the ARRL Antenna Book, understand it, but end up doing it my way. Book learning is fine, it gives you a point to start from, but practical experience beats it out any day. I'm not criticizing you in any way, but poking holes in what is generally accepted as THE Antenna Theory of today. In my considered opinion, the ARRL Antenna Book may be entirely correct at frequencies above VHF, but on H-F, MW, VLF, and low VHF it is just a good guideline to start from.

The Wireman has #18 copper clad for $6/100' and #12 solid copper harddrawn wire for $15/100. You can go to Lowe's and get a 500' spool of #18 stranded, insulated wire for $50.

I bought a 500' spool of the #18 copper clad and it's been good wire.

I don't know where you have been looking, but I sure wouldn't use steel cable for antenna wire to save a very few dollars.

Thomas, was this meant for me ? I do not have any questions about antenna efficiency, but nice article anyway. Linear Loading is a nice way to go for shortened verticals.
BTW, my background has been in Oceanographic Instrumentation for a number of years.
I would be interested in what you do and you can email me off list.
My antenna is described at http://k3zxl.com/Tower_Vertical/

binary is a form of zero’s and ones. You count from the right to the left. First number is either 1 or 0. Then you just double the number as you go to the left. Its really interesting and when I did assembly language programing I used it a lot.

So 10 in binary is 2.

I run 300 ohm into the shack but mostly qrp, occasionally 100w and used to run 500 with no problems.
It probally depends on a lot of things.

Just reading this terrific paper on basic antenna knowledge and if you
read the first paragraph on page #21 about half way through that paragraph
you will find a wonderful answer to your question!

8' surf rod with an ancient Penn spinning reel (flea market special) , 40 lb spider wire and 2 or 3 oz "bank sinkers". lighter than 2 oz wont always pull the spider wire to the ground. heavier than 3oz is hard to control for casting accuracy. easily good to 80'. Not where you wanted it ? never and I mean never pull the sinker back through the tree 75% of the time it gets caught. I tie a piece of pink florescent plant tie to the bank sinker so I can see it better in the woods. Once over the tree I pull parachute cord back through the tree with the spider wire then use the parachute cord to pull heavy rope.

I find the idea of the spud gun for accuracy appealing maybe I'll put it on my Xmas wish list some year . As one poster noted earlier there is the potential for spud gun explosive accidents if not used properly. Surf casting rods never explode but as noted above the unintended consequence of trying to pull a fouled bank sinker from a tree can result in a bank sinker coming back at you out of the tree at amazing speed , fortunately I was wearing a hard hat ...now I never try to pull sinkers back through only lines :-)

The closest lowes or home depot to me is in brenham or bastrop and I don't drive . as for using the steel wire , I have no complaints . have worked greece , croatia , ducie island , christmas island and cuba with it and it has not rusted yet . it is usually pretty damp in south texas except for this year . plus it is light weight and does not tangle the way bare copper wire does .

For wire antennas I have had great success with one of the pneumatic tennis ball launchers getting over 100 foot plus trees. The two big things about these is they shoot the brightly coloured and weighted tennis ball with accurate aim and the tennis ball with about 4 oz of BBs makes it down through the branches without getting hung up.

As they are compressed air with a pressure gauge, I feel they are safer than an explosive gas mixture. Plus with the pressure gauge, I find it does not take long to learn what pressure is good for different heights and angles.

Subject: Re: [ham-antennas] Spud Guns

8' surf rod with an ancient Penn spinning reel (flea market special) , 40 lb spider wire and 2 or 3 oz "bank sinkers". lighter than 2 oz wont always pull the spider wire to the ground. heavier than 3oz is hard to control for casting accuracy. easily good to 80'. Not where you wanted it ? never and I mean never pull the sinker back through the tree 75% of the time it gets caught. I tie a piece of pink florescent plant tie to the bank sinker so I can see it better in the woods. Once over the tree I pull parachute cord back through the tree with the spider wire then use the parachute cord to pull heavy rope.

I find the idea of the spud gun for accuracy appealing maybe I'll put it on my Xmas wish list some year . As one poster noted earlier there is the potential for spud gun explosive accidents if not used properly. Surf casting rods never explode but as noted above the unintended consequence of trying to pull a fouled bank sinker from a tree can result in a bank sinker coming back at you out of the tree at amazing speed , fortunately I was wearing a hard hat ...now I never try to pull sinkers back through only lines :-)

Maybe there was a rule change, but currently the only limitation on eligibility for DXCC awards I can see is that all QSL's submitted be made from the same DXCC entity.

There is a milage limit on QSL's for WAS.

Al is correct about DXCC (move as much as you want inside the continental USA) and WAS (must be made basically from the same location) ..it has been that way for at least 30 years

That having been said DXCC is not that hard to do (bragging rights follow) ...Having gotten back on the air for the first time in 10 years from my new QTH I decided to start (DXCC) over just for the fun of it. I started on November 1 of this year running 100 watts and a 25 year old butternut vertical and worked 152 countries in 35 zones in less than 3 weeks (before CQWW-CW). . BY CQWW I had the linear working again, had a _poor inverted L for 160 (_ though I did work CN2R barefoot on 160 with it). I since replaced the "L" with a "T" (much better) and a couple of more dipoles up and picked up 30 more countries and 4 more zones... I just need zone 2 for WAZ.

Working DX is more about being on the right frequency at the right time. The key to that is access to a DX packet spotting cluster or an online service like http://www.eham.net/DX/. Next is timing and listening ability. most of the rare stuff is working split ("up 1") figure out where the DX station worked the last guy (up 1.52) and zero beat. Wait a few seconds before you dump your call in, other stations on the same freq will have ended their calls on top of each other and there you are in the clear etc. Some DX slide their listening freq up and down after each QSO figure out which way he is sliding and anticipate him by moving up 100HZ from the last station he worked and so on ....listen , listen listen ...yeah big antennas, way up high with a full set of bottles will get you through the pile up quicker but technique goes a long way for getting a modest station in the other guys log.

I once made an end-fed zepp with 1/4 wave open wire feeder for 20m. I was still just an SWL but it made an excellent receive antenna.

You can lift the ground of the tuner and measure common mode current
If common mode current is zero and no other ground is there all power is on
the ladderline and no ground current means balanced load
...
Another way would be measure both currents (in both legs)

I'm going to wind my first 4:1 balun and no matter how much I read I cant find the same answer twice so why not ask. I'm using a T200B-2 core and silver plated Teflon covered wire #16. First question, why do some of the how to's want you to wrap the toroid core in tape and other don't?, secondly, even though all are saying they produce a 4:1 for HF why do the number of turns vary so much? Lastly, when they say 14 or 16 turns I'm assuming they mean "total" turns, both sets of windings, IE (8 on one side 8 on the other)?

Topic: 20989 Message: 20990

Some wrap the core or rods because they need more insulation between the wire and core. I only wrap bare rods. You won't need it because of the heavy insulation provided by the Teflon. Some magnet wire that is designed for motor use has a thin coat, other magnet wire has a much thicker coat.

The number of turns will depend on the wire insulation and core type. When you complete you winding you can do it with , let's say one more winding, then check the resonate frequency of you balun. It would be easier to remove a winding than add one.

A note about winding with Teflon wire, it is a little harder to hold in place than magnet wire. It will spring back or unwind. I use little spring clamps or paper clamps and hold the wire in place, apply some quick set epoxy. When doing a 4:1 current balun a torrid I use little alligator clips I got at Harbor Freight to hold the spacing until the epoxy dries. On a rod type I use monofilament fishing line to hold the spacing.

Thanks for the reply, I have at least one more question though. I’m seeing anything from 12 to 16 turns (I assume per side) using a T200 core, from what you’ve said I probably should error on the more side and use the 16 turns per side? Does more turns reduce the effective frequency from say 3.5 to 1.8 mHz while possibly dropping the upper end also?

Jim you are on the right track but headed the wrong way. You want more turns for 1.8 and 3.5 , less for 14 thru 29 MHz.

This is just my point of view, I do not work 160 so when I am building a balun for myself I adjust the windings so I get a 1:1 SWR in a dummy load at 10MHz. I have made a similar balun for a friend who has 6m and was planning a multiband loop so I made it with less turns giving higher readings at 3.5 but better at 54.

Note that my number of turns I would not relate to your set up due to different core materials and wire type I used.

You've been very helpful, I'm starting much like medicine this might be as much art as hard science I did order MFJ's cheapest swr analyzer because I believe it's now a justified expense. The problem with MFJ is the past 2 things I've ordered from them were on back order. Why things are allowed to be sold that aren't in stock is beyond me. I really think we are lucky to have MFJ, but things could be a little more consumer friendly...

Thanks to a member of this yahoo group, I will be obtaining a alpha-delta DX-lb. I want to take the fan dipole design and add 60 and all of the WARC bands. Considering the bandwidth of 60 meters and WARC, full coverage should be possible. Anyone done this before? Any interaction between wires?

I want to purchase alpha-delta wire seperators, if they sell them, if not, I will use PVC.

Any thoughts or comments?

Jim

For Xmas you might want to ask the XYL to get you a copy "Transmission Line Transformers" , by Jerry Sevick , W2FMI (deceased). Probably one of the most informative, exhaustive practical books on the subject

. I bought my copy 10+ years ago and it was only $20 ..I See ARRL is now selling it for $75 !!!!! (which I think .... are you listening ARRL? .... is a bit unrealistic) , likely you may find a less expensive copy on Evil-Bay or that book seller named after a large river in South America

More directly to your point the number of turns can depend on an number of factors

1) Actual core type
2) Frequency(s) of interest
3) Winding material and style (twisted pairs, parallel wires, coaxial etc), careful choice of the core type and winding style can easily produce baluns which are essentially flat from 1 MHz to 30MHz
4) Also the intended application, i.e. 12.5 ohms to 50 ohms vs 50 ohms to 200 ohms . Sevick found that the characteristic line impedance of the line used to do the winding was important in achieving maximum bandwidth

I know this did not exactly answer your question and in the end without a lot more data I just would wind one and then test it, all part of the learning experience

Yes, I have noticed how ARRL has become a publishing house of EXPENSIVE books.

Geesh, My original Handbook was $3.50 and the Antenna Manual was $2.00. I still use it :)

Now they are $50 each?

Jim , if I need a MFJ product I always get it mine from R&L ,

http://store.rlham.com/shop/catalog/ They have most MFJ products in stock.

They are a little less than MFJ's list price, good service and quick to ship. I have ordered things from them and two days later it will be at my door but then they are in Ohio and I am in Missouri. Most of the time I get a little coax or other items and bump it up to free shipping. I get most of my coax and stuff from them. A quick call to them and they have always been helpful or order on line.

For PL-259's, SO239's, torrids, resistors, IC's and things from my local emporium http://www.gatewaycatalog.com/

I have no connection to these places, it just where I shop.

You will hear a lot of the "ex-sperts" run their mouth about the quality of this or that brand but if it does the job for you and me then it's good enough. I have a good Fluke true RMS meter at my bench but when I am at a friends or field day it is a simple Craftsman meter in my tool bag.

I remember when I bought my Signalink USB interface, there was a wait, they were sold out and had to wait until the next shipment of boards arrived from overseas so the product could be assembled on the west coast then shipped to me. I hope you get your meter soon.

(Note that my number of turns I would not relate to your set up due to different core materials and wire type I used.)

You've been very helpful, I'm starting much like medicine this might be as much art as hard science I did order MFJ's cheapest swr analyzer because I believe it's now a justified expense. The problem with MFJ is the past 2 things I've ordered from them were on back order. Why things are allowed to be sold that aren't in stock is beyond me. I really think we are lucky to have MFJ, but things could be a little more consumer friendly...

I have found several sites on Google.

http://www.hamuniverse.com/multidipole.html

http://www.eham.net/articles/12399

http://www.qsl.net/kd7rem/antdipole.htm

These are very interesting web sites.

I personally have an inverted V fan dipole. They are a 75/80 M going N/S and a 40 M going E/W. They are resonant on 75/40/15/12/10 so no need to use a tuner on those bands. With a tuner I can tune the rest of the frequencies. I have a SB-200 Heathkit 500 W Linear Amp but hardly ever use it. I turn it on one a month to keep it working.

My question is why not make your own antenna instead of buying it. Of course the cost of wire has gone up a lot since I put up mine.

Thanks to a member of this yahoo group, I will be obtaining a alpha-delta DX-lb. I want to take the fan dipole design and add 60 and all of the WARC bands. Considering the bandwidth of 60 meters and WARC, full coverage should be possible. Anyone done this before? Any interaction between wires?

I want to purchase alpha-delta wire seperators, if they sell them, if not, I will use PVC.

Any thoughts or comments?

That is a good book but now that it is out of print the price seems to track with the price of a ounce of gold. You can still get Jerry Sevick , W2FMI book “ Understanding Building and Using Baluns and Ununs” for less than $20 from several places. It will have everything you need, it is still in publication. It does not get into the depth of the math theory as deep but if you want to build and not just study numbers it is what you need. It covers 1:1 up to 12:1 and everything in between. I have it and would highly recommend it. I got mine from,

http://www.universal-radio.com/catalog/books/0558.html

R&L have great prices and great service. Have ordered coax and many other things from them. I used the info from the arrl hand book to build my 4:1 baluns and then checked with the analyzer with a 200 ohm resistor connected across the connections. I have made two of them and they both worked out really good.

I have not done this myself with a Alpha-Delta. I would wonder how wires would interact with the traps.

I did make a 5 band fan dipole from scratch. Here is the good, bad and the ugly of doing it. I cut the wire for where I wanted to operate on 75, 40, 20, 12 and 10. I put it up and it was only good on 75. I lowered it and added wire as required for each band, 40 first the on up. Do not start on ten, work the lower bands first. I would advise to cut longer and tweak as required. The difference will vary according to your spacing, wire size and so forth. It worked OK all summer, then winter came as did the snow and ice. My PVC spacers broke loose at the epoxy so in the spring when an old man's fancy turns to antennas I lowered it back down and did a little cleanup on the copper and reset the spacers. Then took some 22ga solid tinned wire did wrap across each spacer and soldered it to the antenna. Now it holds up in sleet and snow.

Here is a picture of it up in the air.

I put up a fan dipole 2 years ago and it has been a great antenna. My fan dipole is all inverted vee and has a dipole for 80,40,30 meters. 17 meters comes out with about 1.4 swr with no tuner. 12 meters loads up pretty good with the tuner. I have worked lots of dx on the antenna and has been the best antenna I have built so far. You have to start by tuning the lowest band of frequency and then trim the dipoles as you go up in frequency on the dipoles. Keep the dipoles spaced as far apart as you can. My 80 runs E to W. The 40 runs NW to SE. The 30 runs E to W below the 80. Give it a try you will be surprised.

Dean, I read the above in your post.

The part about your fan dipole being "resonant" on 5 different bands intrigues me.

What test method and what test equipment did you use to determine antenna resonance on those 5 bands?

Thank you.....

Yes, a low SWR does not mean resonance. \My dummy load is low SWR and certainly not resonant.
The T2FD antenna has a reasonably low SWR but as Cebik verified in his report on this antenna,
it is slightly better than a dummy load at low frequencies of 160, 80 and 40 meters.Like -6 dbd at 80 meters

I also have been using a fan parallel dipoles on 40 to 17 for 3 years.
I do not need a tuner on those bands but on 15, 12, and 10 it requires a tuner.
The antenna works well but was touchy to get tuned up as I did not leave enough space between the wires.

The weather and sun has taken its toil on the plastic hanger spreaders, it was a prototype after all,
Since I will be moving soon, I will be rebuilding it in about 3 months to have about 1 meter between the ends
of the wires and the feed ends will be about 1 foot apart with the feed at the bottom of the stack.
That should allow better tune up of the individual dipoles. I will use plastic pipe as spreaders. I have used
the pvc pipe for years as antenna supports and coil forms with good results. I know there are some who
knock it but it seems to work for me. However at VHF I have found it will affect lengths due to velocity factor.

The test equipment was a Kenwood 440S. Trimmed the 75 meter and then the 40. When it was resonant for 3.8 to 4.0 and the 40 is resonant from 7.125 to 7.300 minding the band edges of course. The other bands work because of harmonics. If I want to do 17 meters I need to use my radio tuner which tunes them very well. The only frequency that has a problem not tuning is 20 meters and for that I need an external tuner. If I never use my amp then this setup works very well for me. When the antenna was first put up I had a General license so 75/80 was set at 3.8 Mhz. I can take it down to 3.6 if I use the tuner in the radio but my amp won't tune it down to 3.6 without higher SWR's. My dipole is different than most of the inverted V fan dipoles I have seen. One end drops about 20 degrees and the other drops down about 60 degrees. I live on a side of a mountain. If I was to put my dipole further back on the edge of the bluff I could get the same angle on each side. Of course if I put up a 50' pole I could make them the same angle. The antenna works very well for me so no reason to change it.

I hope this helps you. I could take pictures but you would probably never see the antenna. It blends into the sky real well. I have 8 acres and I would love to put up a 75 plus foot tower by the house. All this old man can afford though is dipoles. Where I could really put of a lot of antennas the ground is 15' lower than my house.

This is not from Dean but I did mine 5 fan dipole band the first time with a radio (TS-450) and a 30 year old SWR meter. The next year I use a MFJ-259B but both ways will work, you can spend a lot more on test equipment if you so desire but I am cheap. I call looking at a point of resonance where I get a good SWR and indicating power out. A low SWR may not be a true point of resonance but the radio likes it. You could call mine a 6 band if you want to work 15 on the 40M section but a 1.5 wave antenna, 3/4wl each side is a 100 ohm antenna and the best you can get in theory is 2:1. Also remember with height changes the SWR can change.

From: dean
Topic: 20994 Message: 21011

Lee if you have the parts experiment with different set ups. Is my dipole the ideal dipole? Maybe not to someone else but it works for me. My first Elmer and one of the local VE's set up my antennas for me as I am disabled and couldn't do it on my own.

In the long run to can talk to 100 different hams and get 105 different answers. Just have fun.

>> I personally have an inverted V fan dipole. They are a 75/80 M going N/S
and a 40 M going E/W. They are resonant on 75/40/15/12/10 so no need to use
a tuner on those bands.
>> 73, WY6L

Dean, I read the above in your post.

The part about your fan dipole being "resonant" on 5 different bands
intrigues me.

What test method and what test equipment did you use to determine antenna
resonance on those 5 bands?

Thank you.....

Lee KA0FPJ

This is not from Dean but I did mine 5 fan dipole band the first time with a radio (TS-450) and a 30 year old SWR meter. The next year I use a MFJ-259B but both ways will work, you can spend a lot more on test equipment if you so desire but I am cheap. I call looking at a point of resonance where I get a good SWR and indicating power out. A low SWR may not be a true point of resonance but the radio likes it. You could call mine a 6 band if you want to work 15 on the 40M section but a 1.5 wave antenna, 3/4wl each side is a 100 ohm antenna and the best you can get in theory is 2:1. Also remember with height changes the SWR can change.

21012. 60 meter and WARC bands on fan dipole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-07 00:00:00 UTC
From: Robert Costa, KB6QXM
Topic: 21012 Message: 21012

All,

Thank you for all of your replies. I appreciate the information. My question was posed as if anyone had done a 60 meter and WARC on a fan dipole. I did receive a lot of information and some technical banter back and forth, but no one said that they have done it and here is how they did it.

So I guess I will have to experiment and hope for the best. I do not care about the other bands as I have another dipole for the other bands.

Thank you all for your replies.

>> Lee if you have the parts experiment with different set ups.

Yes....I did that this past Spring. I was looking for a Field Day antenna. It was an enjoyable project. I made a "fan dipole" that I used on 15,20, and 40 meters. My Yaesu FT-450 has a built-in tuner, but I _DON"t_ use it with this antenna. It's not necessary.

THis antenna has now become my "go to" antenna for camping. As long as there are nearby trees within slingshot range.

I'm not prepared to say that my fan is "resonant" on any of the above bands, but it is functional, and the radio stays happy.

Over the years, I've become moderately sensitive to the "loose usage" of the term "resonance" as it applies to antennas. I'm 68 years old, licensed in 1979.

I've sure enjoyed home-brewing of antennas, and I've built some awful ones!!!! Used up a lotta wire. But then again, some of 'em worked pretty darn good. If I wasn't so _TIGHT_ I'd buy an antenna analyzer!!! I am fortunate in that I own 2 of the military grid-dip meters. They are certainly an asset for antenna building.

From: Jim Whitaker
Topic: 20989 Message: 21015

(R&L have great prices and great service. Have ordered coax and many other things from them. I used the info from the arrl hand book to build my 4:1 baluns and then checked with the analyzer with a 200 ohm resistor connected across the connections. I have made two of them and they both worked out really good.)

I like the sound of that! A good balun costs quite a bit for as simple a thing as they appear to be. And just reading the sales pitch doesn't help at all. They all say legal limit, and DC to daylight! From what I've read thus far, that is mostly under "ideal" circumstances and not the real world, kind of like antenna gain specified against isotropic

A low SWR may have nothing to do with "resonance". The two terms are unrelated.

A full wave dipole ("two half waves in phase") will be "resonant" on a frequency but with a very high feed impedance and a very high SWR.

Actually an antenna has a very small "resonant" frequency range (unless you are using extremely large conductors such as a cage). An antenna may have a low SWR across the 80/75m band but it will only be "resonant" on a single frequency in the band.

Lee,

That is correct and you are right, keeping the transmitter happy should be the primary goal.

There is nothing special about the 60m band as far as a fan dipole is concerned. You can add any number of elements to a fan dipole. If you get make enough elements, it becomes a broad frequency "log periodic" type of antenna ;-) However, the more elements and the closer the spacing, the more interaction.

Subject: RE: [ham-antennas] 4:1 Balun winding questions please?

Some wrap the core or rods because they need more insulation between the wire and core. I only wrap bare rods. You won't need it because of the heavy
insulation provided by the Teflon. Some magnet wire that is designed for motor use has a thin coat, other magnet wire has a much thicker coat.

The number of turns will depend on the wire insulation and core type. When you complete you winding you can do it with , let's say one more winding, then check the resonate frequency of you balun. It would be easier to remove a winding than add one.

A note about winding with Teflon wire, it is a little harder to hold in place than magnet wire. It will spring back or unwind. I use little spring clamps or paper clamps and hold the wire in place, apply some quick set epoxy. When doing a 4:1 current balun a torrid I use little alligator clips
I got at Harbor Freight to hold the spacing until the epoxy dries. On a rod
type I use monofilament fishing line to hold the spacing.

Rich, Kd0zz

Subject: [ham-antennas] 4:1 Balun winding questions please?

I'm going to wind my first 4:1 balun and no matter how much I read I cant find the same answer twice so why not ask. I'm using a T200B-2 core and silver plated Teflon covered wire #16. First question, why do some of the how to's want you to wrap the toroid core in tape and other don't?, secondly, even though all are saying they produce a 4:1 for HF why do the number of turns vary so much? Lastly, when they say 14 or 16 turns I'm assuming they mean "total" turns, both sets of windings, IE (8 on one side 8
on the other)?

21025. J-poles --> Insulated stub?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-07 04:35:59 UTC
From: Todd F.
Topic: 21025 Message: 21025

I've hunted all over, but I can't find anything on this.

I've seen some designs for J-poles that insulate the stub from the main element instead of the typical electrically-continuous (at least for DC) pipe or rod with two feed points (center on one and shield on the other) . Frankly, I don't know enough about antenna design or RF behavior to understand how the typical j-pole arrangement works. It looks like a pretty good ground or power bus to me, but I still mostly think in DC rather than RF AC.

Any thoughts on the insulated-elements issue? A micro-tutorial on j-pole theory?

Many thanks!

Jim that DC to Daylight is what got me into doing my own baluns. I tried one of the older ham call sign named, store bought balun that covered everything from 160 and up. Well not too good on a solid state radio, might have been ok on a older tube radio like my Johnson rig. I built a voltage 4:1 balun , it was easy and it worked. I then built a current one on a torrid, next on twin torrids with a acrylic spacer and at last twin rod type for the widest range of good SWR readings. I now use it on a multiband loop antenna as my main antenna set up.

I still have trouble knowing what PEP is. The old DC input was simple. 4000 volts times 250 milliamps equaled 1000 Watts. That was a REAL killowatt.

Subject: RE: [ham-antennas] 4:1 Balun winding questions please?

. And just reading the sales pitch doesn't help at all. They all say legal limit, and DC to daylight! From what I've read thus far, that is mostly under "ideal" circumstances and not the real world, kind of like antenna gain specified against isotropic

Jim that DC to Daylight is what got me into doing my own baluns. I tried one of the older ham call sign named, store bought balun that covered everything from 160 and up. Well not too good on a solid state radio, might have been ok on a older tube radio like my Johnson rig. I built a voltage 4:1 balun , it was easy and it worked. I then built a current one on a torrid, next on twin torrids with a acrylic spacer and at last twin rod type for the widest range of good SWR readings. I now use it on a multiband loop antenna as my main antenna set up.
